Nickel-Copper Matte.—The smelters of the Canadian Copper Co. at Copper Cliff and the Mond Nickel Co. at Coniston are turning out nickel-copper matte at an unprecedented rate. The production, as compared with the first 6 months of 1915, shows an increase of nearly 40%. The valuation of the metallic contents of the matte has been made on a basis of 10 cts. per lb. for copper and 25 cts. for nickel. The figures given for metallic copper and nickel separately show that the prices were over 18 and 42 cts. per lb., respectively.

In addition to the above mentioned companies the Alexo mine, near Porquis Junction, produces a small amount of nickel-copper ore, which is treated at the Conister smelter.

Molybdenite.—This mineral occurs widely in Ontario, but is mined chiefly in Renfrew county. It is wanted at the present time for use in the manufacture of high speed tool steel, and for this purpose molybdenum will probably replace tungsten to some extent. The demand for molybdenum steel to be used in munition factories comes largely from the allied nations—Britain, France and Russia. Molybdenite concentrates containing 85% or more of MoS₂ are worth about \$1 per lb. Ferro-molybdenum is now (September) being manufactured for the first time in Canada by the Orillia Molybdenum Co. at Orillia, and the Tivani Electric Steel Co. at Belleville.

Iron Ore and Pig Iron.—The only shipments of iron ore were from the Magpie mine, operated by the Algoma Steel Corporation of Sault Ste. Marie. Although iron ore production shows a decrease as compared with the same period in 1915, that of pig iron shows a material increase, both in tonnage and value.

Improvements of Burro Mountain Copper Co.

VIEWS OF RECENT IMPROVEMENTS OF THE BURRO MOUNTAIN COPPER CO. AT TYRONE, N. M.

1. The T. S. Parker Hospital, costing \$75,000. 2. Interior view of power plant equipped with two Diesel oil-burning engines. 3. Exterior view of power plant, which equipped cost \$300,000. 4. The 1800-ton concentrator, representing an outlay, with its equipment, of \$1,000,000. 5. Group of steel-concrete houses for employees; 100 have been completed.

Graphite Development in Burnet County, Texas.

ALVIN STRONG.

The first 50-ton unit of a 200-ton mill for concentrating graphite on the property of the Texas Graphite Co., 11 miles northwest of Burnet, Tex., will soon be in operation. The three other units will be completed as rapidly as the machinery, which has already been ordered, arrives.

Mining will be all open-cut work for a long time to come. The deposit is 400 ft. long, 200 ft. wide,

FIRST UNIT OF TEXAS GRAPHITE CO.'S MILL.

proved to a depth of 100 ft., and is enclosed between perpendicular granite walls running northeast and southwest. The schist in which it occurs runs from 8 to 12% graphite in its crystalline form. It is estimated that 3 weeks' mining will supply sufficient material to keep the mill running for 3 months. It is expected that all four units of the mill will be in operation before the end of September.

The company is a holding one, capitalized at \$100,000, officered as follows: P. B. McCabe, president;

LABORATORY OF TEXAS GRAPHITE CO.

Dan McFarland, vice-president; Jos. Pangle, secretary-treasurer. The plant in full operation will employ 12 mill hands to each unit, while other work will bring the total employed during periods when mining is in progress up to 100. Seventy men are now employed at the camp.

A shaft is being sunk in a ravine which skirts the camp in the hope of securing enough water to run the

mill. In case the shaft does not tap a sufficient supply, tunneling will be resorted to at water-bearing levels. If this fails, a pipe line will be laid to the Colorado river 3 miles away, and water will be pumped to the mill against a head of about 160 ft.

The concentrates from the mill will be shipped to Jersey City, N. J., for refining, a plant being now under construction at that place for this purpose.

California's Mineral Production.

F. McN. HAMILTON.*

The mineral output in California during the year 1915 amounted to \$96,663,369 worth of crude materials. There were 49 different mineral substances, and of the 58 counties in the state all but two contributed some mineral product.

As compared with the 1914 output, the two notable features are the almost startling increases in some of the metals, and the decrease in petroleum, both in quality and total value. The result, however, is a net increase in the grand total value of \$3,348,596 over the 1914 total.

Of the metals, antimony again entered the active list after an absence of several years. Copper increased over 10,000,000 lbs. in amount and \$3,114,192 in value. Gold increased \$1,788,800. Quicksilver increased 25% in amount and more than doubled in value. Tungsten increased from a value of \$180,575 to \$1,005,467. Zinc increased from 399,641 lbs., worth \$20,381, to 13,043,411 lbs., valued at \$1,617,383!

Petroleum decreased approximately 12,000,000 bbls. in amount but the average price per barrel was slightly higher, so that the net results was a decrease in value of \$3,983,272.

California yields commercially a greater number and variety of mineral products than any other state in the United States, and possesses latent possibilities in other items as yet undeveloped. The total annual value of her output is surpassed by but four other states—they being the great coal and iron producers east of the Mississippi river. Of several items, including borax, chrome and magnesite, California is the sole producer. For several years California led all others in gold, petroleum, platinum and tungsten.

Zinc and molybenite have recently been found in New Zealand. The deposit containing the molybdenum was discovered at Takata and the samples assayed were found to contain 50% molybdenum oxide. Ore declared to be pure sulphide of zinc has also been discovered at Wangapeka, 53 miles from Nelson. The reef is from 4 to 5 ft. wide and the ore is said to run 18% zinc.

The total production of explosives, excluding exports, according to Bureau of Mines figures, was 460,900,796 lbs., as compared with 450,251,489 lbs. in 1914.

*State Mineralogist.

Chicago Meeting American Mining Congress

Carl Scholz, president of the American Mining Congress, speaks enthusiastically of the coming convention which opens Nov. 13.

"As a resident of Chicago I personally urged the congress to hold its convention for 1916 here," said he, "feeling that this is really the center of trade, industry and transportation. Now that the local committees are in the midst of their labors, I find that the selection was in every way ideal. The greatest experts in metal, coal and oil have already promised to be here. The governors of all the states are appointing strong delegations, and it looks as though we would be able to crystallize the sentiment of the entire country on several important issues, notably those of mine-law revision and of added mine safety.

"People generally fail to realize the vast importance of these meetings. Here is where, often, the most important and epoch-making legislation begins. As an illustration, the establishment of the Bureau of Mines was the work of the American Mining Congress. The Federal Trade Commission is in a way the creation of this congress. While the bill adopted by congress differed materially from that suggested by us, it had the approval of Mr. Davies, the first chairman. In fact, it was his prediction that every feature in the American Mining Congress measure would eventually be adopted.

"The American Mining Congress is also the inspiration for most of the distinctive coal and metal men organizations of the country. For it was the American Mining Congress that first brought together the producers of coal and metal so that they were able to work to better ultimate results than heretofore. It was our initiative that brought co-operation in the matter of establishing uniformity of sales terms, uniformity in the preparations for production and, above all, the adoption of more efficient methods of construction in mining. I do not wish to say that the American Mining Congress claims the credit for all these things. But it was at the meetings of the congress that the metal and coal men first met, and at these gatherings was born the determination to work together to consult and co-operate.

"The advance in metal prices due to the European war has in no way lessened the great work of the American Mining Congress. In fact, many of the papers to be read by experts at the coming convention will deal with this problem of preventing disintegration after the war and a return in mining fields to the lethargic conditions of a few years ago.

"We intend to have an absolutely fearless discussion of the labor question. Col. George Pope, president of the American Manufacturers' Association, has agreed to discuss the subject from his standpoint, and we will have either Secretary of Labor Wilson, or some one as authoritative, reply. Of course in many of the states, such as Ohio, Indiana, Illinois, Iowa and Pennsylvania, contracts govern the mine labor situa-

tion. But in the far west the situation is very different. In fact, it is the purpose of the congress to formulate a plan for labor legislation and regulation on which all sides of the controversy can to an extent agree.

"In the matter of safety work there will be some excellent papers read, and I look for some illuminating discussions. Right into this discussion I hope to have injected some remarks on the necessity of preparedness, for after all in the matter of safety the co-operation of employes is just as essential as safety methods adopted by employes.

"As a matter of fact, 90% of the so-called efficiency is the willingness of the rank and file to accept orders from people who know their business. It has been said that men become machines in the German army. That is far from true. They simply learn what every subordinate should learn, obedience to the man who is directing operations.

"I have just returned from attendance at the Arizona meeting of the American Institute of Mining Engineers. While there I was asked to speak on the essential difference between that body and the American Mining Congress. I told them that I deemed their body the medical adviser of capital, for their business is to advise on investments. And the American Mining Congress is the spiritual adviser to all interests in mining. We take up the problems that all have in common and try to find a solution for them by advocating needed legislation and needed reforms.

"While in Arizona at the convention I took occasion to invite to our gathering J. S. Douglas, the man who discovered what may possibly be the greatest copper mine in the world, the United Verde Extension.

"And this reminds me of one great topic which is coming before the convention of the American Mining Congress, and which no man interested in mining can afford to miss—that is the topic of flotation. To the lay mind that means but little. To the mining man it spells revolution in the matter of mining production. Think of it! By the flotation process they are mining profitably copper ore running 1.8%. This process, which is simply the use of oil bubbles to float crushed ore, has put a value of millions into vast tailing dumps.

"And not alone will the government experts discuss flotation, but the men who are making enormous saving in values wherever there are sulphide ores will be in attendance to tell the world how the simplest of ideas, the affinity of a little foaming oil for sulphide ores, is enriching the world by millions and millions—all of which had previously been washed away or gone up in smoke, or was lying in vast refuse dumps at every mine."

Business Affairs of the Meeting.

"Legislation along several lines of great importance

to the west should command the careful attention of all those interested in the development of the western states," says J. F. Callbreath, secretary of the Congress.

Mr. Callbreath says the convention promises to be the largest gathering of mining men ever assembled in the United States and will offer splendid opportunities for the western states to present their claims before prominent citizens of the east, which can give the congressional support necessary to accomplish the results the west needs. Discussing the various issues now pending before congress, Mr. Callbreath said:

"The next session of congress will have under consideration the Foster bill for revision of the mineral land laws of the west. It will be recalled that a bill for a commission to investigate conditions through public hearings in the western mining centers and make recommendations to congress was introduced by Senator Smoot and passed the Senate, but failed to receive the approval of the house committee on mines and mining. In its stead Dr. Foster, chairman of the committee, introduced a bill intended to meet the requirements without the preliminary work of a commission. This bill was severely criticised by the west and the mining journals. A thorough discussion of the subject will take place at the Chicago convention. Dr. Foster himself will lead the discussion and defend the plan he proposes. The discussion will be lively if the critics of his bill meet him on the floor. A plan for future action will probably be outlined, and a campaign begun to bring about the practical legislation desired.

"The question of whether the senate committee amendment to the Ferris land leasing bill shall prevail is of vital importance to the west. Whether the resources of the west are to pay endless tribute to the national government, through a federal leasing system, or be subject to taxation by the states themselves, concerns directly every taxpayer. It is a question of home rule, with the western industries controlled by those who know them, as against control by a cumbersome agency 2000 miles away.

"The question will probably be finally determined at the next session of congress. The bill has passed the house and it is now before the senate. The senate will probably approve the recommendations of the committee, and unless the west rallies to the support of the senate committee recommendations there is grave danger that the house will refuse its approval.

"These and other important questions will be considered at our Chicago convention in November.

"The proceedings of the American Mining Congress convention this year will be held in sections, of which there will be six, each one devoted to a particular branch of mining activity. This arrangement, introduced into the proceedings of the congress this year for the first time, will enable each delegate to give his attention to the particular branch of the industry in which he is interested. Two entire floors

of the La Salle hotel and several rooms on other floors have been engaged for the convention.

"The question of a compensating tariff duty upon imports of lead, zinc and tungsten ores will occupy a foremost place in the discussions of the lead, zinc and tungsten sections."

New Tests for Molybdenum.

In the March issue of the *Journal of the Chemical, Metallurgical and Mining Society of South Africa*, Dr. James Moir gives some new and sensitive tests for molybdenum. The first relates to the formation of a characteristic blue color which ordinarily appears as a fugitive tint in the first stage of reduction of molybdic acid by nascent hydrogen. The author has improved this test and secures a permanent blue color.

Hydrazine, N_2H_4 , forms in the writer's experience the best reagent for developing the blue color. A solution containing a trace of alkali molybdate when acidified with acetic acid and treated with a little hydrazine sulphate and boiled, rapidly turns deep-blue and retains this color on boiling. Hydroquinone may be used in place of hydrazine with much the same result. An analogous but more remarkable reaction is that obtained when a slightly acid solution of MoO_3 is treated with potassium iodide (in some excess) and boiled for some time: iodine is slowly liberated and the solution turns blue. The use of phenylhydrazine for reducing molybdenum has been described by Spiegel and Maas (*Berichte*, 1903, p. 513), but the reddish coloration obtained is different and seems to contain phenylhydrazine. Simple hydrazine is an improvement.

The best known sensitive test for molybdenum is that in which the acid solution is treated with sulphocyanide and a tiny piece of zinc added, when a crimson coloration is obtained in a few seconds. If iron is also present the solution becomes blood-red on adding the sulphocyanide, but on adding the zinc this becomes colorless through reduction (to the ferrous condition) and after a few seconds becomes crimson if Mo is present. If the solution is strongly acid the coloration verges to red and is less sensitive; if nearly neutral the coloration resembles that of permanganate. It is probably due to $Mo(SCN)_3$. Another modification of the test for Mo in presence of Fe is to add stannous chloride to the acid solution until the yellow color just disappears and then add sulphocyanide.

Another well-known reaction for MoO_3 in the absence of iron consists in adding potassium ferrocyanide. Mineral acid must be present, and a russet-brown precipitate is obtained which still contains hexavalent molybdenum.

In the presence of acetic acid (not mineral acid) tannin (or gallic acid) gives a similar reaction, which has been known for some time. The writer has improved this by substituting pyrogallol or pyrocatechol for tannin. Either of these when added to a molybdic acid solution previously treated with sodium acetate gives a very sensitive orange coloration.

What the Mining Companies are Doing

Rochester Mines Co., Nevada.

The following is the report of the Rochester Mines Co. for the period from May 1, 1915, to May 15, 1916:

Bullion sales and other income.....	\$ 533,186.85
Mining and milling costs.....	433,732.47
	\$ 99,454.38
Administrative and general expense.....	46,807.05
Operating profit	\$ 52,647.30
Interest on notes payable.....	6,895.81
Net profit	\$ 45,751.30
Proceeds from sale of stock.....	92,550.50
	\$ 138,301.99
Deduct sale of stock and impairment of capital.....	113,850.49
Surplus May 15, 1916.....	\$ 24,451.50
Assets—	
Cash in bank, bullion, etc.....	\$ 40,722.27
Prepaid insurance	583.55
Outside investments	550.00
Fixed assets	2,161,742.38
Total assets	\$2,203,598.20
Liabilities—	
Accounts payable, taxes, etc.....	\$ 30,355.70
Capital stock, net worth.....	2,173,242.50
Total liabilities	\$2,203,598.20

Nevada Douglas Con. Copper Co.

The company has issued the following statement of its operations for the fiscal year ending June 30, 1916:

Mining	\$ 54,200.94
Maintenance	2,819.70
Mill operations	19,655.72
Western Nevada operations.....	5,522.96
General expense	9,444.90
Revenues	140,175.82
Operating expense	76,490.60
Net operating revenue from mining operations.....	63,775.22
Accrued taxes	1,500.00
Net income after deducting all operating expense.....	11,044.66

Butte & Superior-American Zinc.

J. L. Bruce, general manager for the Butte & Superior Mining Co., is inspecting the properties of the American Zinc Co. in Wisconsin and Tennessee. He will also visit the smelters recently acquired by the American Zinc Co. through purchase from the Granby Co. in Missouri and new properties in the Joplin district.

This inspection trip is preliminary to the announcement of plan on which the Butte & Superior and American Zinc companies may be merged. Both are controlled by the Hayden, Stone and Jackling interests, and the proposed consolidation will give the new company five smelting plants in addition to the most extensive zinc mining properties held by any company in the United States.

Butte & Superior output in August was back to normal, with total ore production, 50,000 tons, from which 14,000 tons of concentrates were produced and 15,000,000 lbs. of zinc in concentrates secured. Recoveries were from 93½ to 94%.

Cost of production increased on account of advance in wages and advance in cost of supplies. This will result in about a 10% reduction in profits over the second quarter. In addition there was a shutdown due to an accident at the shaft that curtailed production. New shafts are rapidly approaching completion, foundations for the new hoist are in, and it is expected to have the hoist in operation by the first of the year.

Miami Copper Co.

Profits approximating \$5,650,000 will have accrued to Miami Copper Co. from operations during the first 9 months of this year—estimating September results. This will be equal to \$7 per share, or more than sufficient to meet a full year's dividend requirements at the current \$6 rate.

Surplus today amounts to about \$5,000,000, which will have been augmented materially by the time the November dividend payment of \$1.50 per share falls due.

Profits for the 6 months ended June 30 totaled \$3,499,000.

It is estimated that profits for the third quarter will approximate \$2,150,000, or 66% of the net for the first 6 months.

Miami has sold itself well ahead at high prices. Although not participating in the big copper sale, Miami has effected sales through the early months of 1917 at prices equaling and in some instances higher than the average to be paid on the big export contract.

The Porphyries.

Production of four of the leading porphyry coppers for August are given in the following tables:

UTAH COPPER.

	1916.	1915.	1914.	1913.

Isle Royale Copper.

The third quarterly dividend of \$1 per share has been declared by the Isle Royale Copper Co. At the present time Isle Royale is milling the largest tonnage of rock in its history, and, what is equally important, for every ton of rock that goes to the two mills which serve this mine, a ton is placed in reserve. The rock is running about 14 lbs. of copper to the ton.

For some time Isle Royale's refined copper output has averaged over 1,000,000 lbs. per month, so that for the current calendar year the mine's production should exceed 12,000,000 lbs., produced at a cost of not far from 13¼ cts. per pound. This figure includes 1½ to 2 cts. per pound for extraordinary development, new shaft sinking, and other expenses of a similar nature.

There is every prospect that for the current 12 months Isle Royale will earn \$1,500,000 net, or \$10 per share on its 150,000 shares. On Jan. 1 last the company had a surplus of

quick assets of \$400,000, so that as long as the present price of copper holds Isle Royale should be able to maintain quarterly dividends of \$2 per share.

For 1917 the official expectation is a production of 15,000,000 lbs. of copper. Incidentally sales of Isle Royale copper have been made for delivery next April at 27½ cts. per pound.

Hollinger, Ont.

The balance sheet of the Hollinger Con. Mines Co. as of Aug. 11 shows as follows:

Assets—	
Capital assets	\$23,592,270.98
Current assets	687,153.94
Gold assets (estimated)	399,919.98
	\$24,679,344.90
Deficit—	
Dividends paid up to August 11th	\$ 1,200,000.00
Amount due shareholders of Acme, Millerton and C. M. & F. Co.	720,000.00
	\$ 1,920,000.00
Profit from operations Jan. 1, 1916, to Aug. 11,	1,697,423.01
	\$ 222,576.99
Assets	\$24,679,344.90
Deficit	222,576.99
	\$24,901,921.89
Liabilities—	
Capital stock issued	\$21,000,000.00
Current liabilities	177,921.89
Unpaid patriotic contribution	4,000.00
Amount due shareholders of Acme, Millerton and C. M. & F. Co.	720,000.00
	\$24,901,921.89

Mining costs during the period mentioned were as follows:

Account	Total	Per ton of ore milled
Exploration	\$ 477.44	\$0.011
Development	20,160.56	.603
Production	77,055.51	1.777
	\$103,693.51	\$2.391

The mill ran 92.7% of the possible running time, treating 43,355 tons. The average value of the ore treated was \$9.61 per ton. Milling costs were \$1.053 per ton.

Goldfield Con., Nevada.

The total production of the Goldfield Con. Mines Co. for July was 26,700 tons of ore, from which resulted the net realization of \$30,016.20. Operating costs are given as follows:

	Per ton ore
Total mining	\$2.88
Transportation07
Milling	2.11
General expense38
Marketing03
Bullion tax03
Filter royalty03
Flotation royalty05
Surface04
Total operating costs	\$5.62
Miscellaneous earnings10
Net operating costs	\$5.52
Construction11
Net costs	\$5.63

Miscellaneous Company Notes.

Net profits of the Tonopah Belmont Co. for August were \$92,636. Dry tons milled totaled 12,364; 2,232,369 ozs. of gold bullion was produced and 199,445.02 ozs. of silver.

That Anaconda favors the building up of a big cash surplus for future needs is evidenced by its continuing the \$2 quarterly dividend. The present disbursement calls for payment of \$4,662,500. Up to the end of this year Anaconda will have paid out in dividends \$7 a share on outstanding 2,331,250 shares, or \$16,318,750, compared with \$4,662,500 disbursed in 1915 and \$5,838,125 in 1914. Production, which is sold up to end of the year, is running at rate of about 340,000,000 lbs. annually. The company is earning at rate of between \$45,000,000 and \$50,000,000 a year, or well over \$20 a share. Anaconda in 1917 stands an excellent chance to earn

over \$25 a share with copper metal above 25 cts. a pound. This would mean earnings of something like \$100,000,000, or about \$50 a share, in 2 years.

For the year 1915 the Quincy Mining Co. earned between \$20 and \$23 per share. Owing to underground disturbances operations at one shaft were cut down for several months. Barring further hindrances the company should produce about 21,000,000 lbs. of copper during the present year. Dividends were paid during the last two quarters at a rate of \$16 per annum, earned despite curtailment of operations.

Six of the Calumet & Hecla subsidiaries are now paying dividends, where in recent years only Ahmeek and Osceola have been the regular distributors of dividends. Thus far in 1916 the Calumet & Hecla Mining Co. has received \$2,226,908 from its subsidiaries, compared with \$866,776 last year and \$245,322 in 1914. The payments this year equal \$22 per share on Calumet & Hecla stock, which compares with previous high record of about \$9 per share in 1913.

Wolverine Copper Mining Co. is now netting close to \$100,000 a month and will continue as long as copper remains at its present price. Once an extremely low cost producer, Wolverine during the past few years has been experiencing radical fluctuations in the matter of costs owing to the varying copper contents of its rock. At the present time the cost is about 9½ cts. per pound, which covers higher wages and bonuses paid miners and the increased cost of supplies.

The Victoria Mining Co. is at present producing about 130,000 lbs. refined copper per month, which will be very materially increased early this month on the completion of the additional compartment in No. 2 shaft, which has been in course of construction for several months. The new hoist started operations a few weeks ago. Thus far in 1916 calendar year profits average \$13,000 monthly, or about \$1.50 a share per annum, which have been applied to cost of new construction. The company has no debt, with present balance of assets amounting to \$135,000.

It is expected that Mohawk Mining Co. will show earnings this year of between \$22 and \$23 per share against \$20 paid out in dividends. The last 4 or 5 months of 1916 will each result in net profits in excess of \$200,000, while present indications point to net for the full year of close to \$2,200,000. If Mohawk maintains the record of earlier months of 1916 an excellent showing as to costs for the year will have been established, the outlook now being for an average of about 8½ cts. a pound, including all charges. The company closed its last fiscal year with a surplus of approximately \$300,000, which has not been encroached upon in the payment of two semi-annual dividends of \$10 each.

The Mason Valley Mines Co. offers to stockholders of record Oct. 14, 200,000 shares of stock at \$5 per share, in proportion of two new for three present shares. Stock has been underwritten. Subscriptions are payable on or before Nov. 1, 1916. President Dodge states that the company has acquired the Gray Eagle group of mines in Siskiyou county, California, consisting of 14 patented claims covering about 256 acres. The company is also doing development work on other properties under option. For the 8 months to Aug. 31, 1916, total income of the company was \$12,133 and expenses \$69,710, or a net loss of \$57,576. Current assets on Aug. 31 totaled \$336,772, and current liabilities, \$37,303.

According to present indications Utah Con. Mining Co. will this year make net profits of between \$6 and \$7 per share. This would permit of an extra or increased distribution over the \$3 dividend rate now being maintained. Provided the mine yields for the balance of the year copper and lead at current rate of production of about 1,000,000 lbs. monthly of the former and 1,500,000 lbs. of the latter, Utah Con. will have turned out in 1916 about 12,000,000 lbs. of copper and 18,000,000 lbs. of lead, comparing with 9,000,000 lbs. and 17,000,000 lbs. respectively in 1915. Higher wages and greater cost of materials have naturally been reflected in increased cost of production and the estimated earnings of at least double the present dividend requirements were arrived at after making due allowance in this item. In addition to the income from its own mining operations Utah Con. has an investment in 8250 shares of Anaconda.

WHO'S WHO IN MINING.

Dr. James Douglas, this week's subject of "Who's Who in Mining," is as responsible as any one man in the country for the wonderful advances made in the treatment of copper. His work, particularly in the hydrometallurgical treatment of copper and other methods for extracting the metal from its ores, places the mining industry in unquestionable indebtedness to his wonderful inventive genius.

Dr. Douglas was graduated in 1858 from Queen's University, Kingston, Canada: was professor of chemistry at Morrin College, Quebec, for a number of years, coming to the United States in 1875 to take charge of the copper works at Phoenixville, Pa. Later he became identified with the copper industry of Arizona. He is president of Phelps, Dodge & Co., the El Paso & Southwestern railroad, the Copper Queen Con. Mining Co., and is connected in various official positions with other copper and industrial corporations.

He is a member of the leading societies and has been honored by their highest offices. As a writer he has several notable works to his credit, and he is also a frequent contributor to mining societies' publications and to the technical press.

September Dividends Largest in the History of American Mining.

When dividends of \$78,772,612 were paid in the 9 months of 1913 by 146 American mines and works it was thought that the zenith had been reached. But this record has been far outclassed by the declarations of 155 companies during the 9 months of 1916. According to reports made to Mining and Engineering World, these companies divided among fortunate shareholders the magnificent sum of \$165,675,300. This is equivalent to nearly 25% of the total dividends paid during the last 10 years. With the exception of 1908, when disbursements amounting to \$32,351,450 were paid during the 9 months' period, dividends have been fairly regular, ranging from approximately \$45,000,000 up.

September proved the most remunerative in point of dividends paid of any single month in the history of the industry, when disbursements totaled \$29,551,869, but \$2,799,581 less than was paid during the first 9 months of 1908. Of the September payments the coppers were responsible for \$17,169,994, the gold-silver-lead-zinc properties \$7,243,744, and the metal-

lurgical companies \$5,138,131. Owing to the fact that a part of the earnings of the securities-holding companies are derived from holdings in other companies, their dividends are not included among those paid by the so-called operating companies included in these reports. The \$4,200,000 declaration of the Kennecott Copper Corporation and a goodly part of the \$3,600,000 of Phelps, Dodge & Co., besides others, could rightfully be added to the total for the copper properties, as these earnings were derived solely from operations of properties directly owned by them.

For a record of achievement by a single industry the performance of American mines and works in the years past is little short of wonderful, for the companies paying dividends in 1916 have made disbursements since their incorporation totaling \$1,236,373,691—this on an outstanding share capital of \$925,428,697. Should the dividends paid in previous years by companies not included in the 1916 dividend payers be added to the above total, we would have a total running well up in the billions.

Of the \$165,675,300 paid during the 9 months of 1916, the coppers contributed practically one-half, or \$80,763,234, with 38 companies participating. To date these 38 companies have enriched shareholders to the extent of \$651,833,960, on an issued capital of \$346,146,618.

Owing to the close relationship of the four metals, gold, silver, lead and zinc, dividends paid by companies operating this class of properties are classified under the one head—gold-silver-lead-zinc. One hundred eleven of these properties were not so far behind the coppers, for they divided among shareholders \$66,503,509. To date these companies have disbursed \$369,412,804, on an issued capitalization of \$307,970,039.

Of the 111 companies mentioned above 85 operate properties in the United States, and during the 9 months of 1916 paid dividends amounting to \$55,720,525, and since incorporation \$282,847,294 on a \$196,644,778 outstanding share capitalization. Twenty-one are Canadian properties, with \$7,519,355 for the 9 months' period and \$67,831,042 to date. But three Mexican companies report dividend payments in 1916—these paying \$1,043,629.

The six metallurgical companies had the best 9 months' period in their history, dividing among shareholders \$18,408,557. To date these companies have paid dividends totaling \$212,066,927, on an outstanding share capital of \$270,003,040.

Eight securities-holding corporations have had a remarkable 9 months' period, for they divided among shareholders no less than \$37,973,081. To date these companies have to their credit \$155,424,205 in dividends.

The following is a list of companies paying dividends in September with the date of payment the amount per share and the total amount paid. For dividends by these companies in previous months and

by companies paying dividends prior to 1916, see tables published elsewhere in this issue:

In the United States District Court, Wilmington, Del., Judge Bradford filed an opinion in the case of the Minerals Separation Co., Ltd., a corporation of Great Britain, vs. Miami Copper Co. Suit was brought for alleged infringement of three United States letters patent for processes relating to ore separation. Three claims of patent number 835,120 were in suit and of these, two were sustained by the court, and held to be infringed by defendant; while the third was held to be invalid as being too broad. Several million dollars are involved in the suit. In reply to an inquiry an official of the Miami Co. states that the decision only affects a comparatively small additional saving that is made by flotation as the bulk of its recovery of copper is by table concentration. Counsel for the company are confident that the decision will be reversed by the higher courts.

On another page of this issue will be found an interesting description of Cripple Creek mine operations, which include the driving of the great Roosevelt tunnel. This latter work is being carried on quietly and without any of the usual trumpeting following such an immense undertaking, but its completion will be of untold value to the mines benefited, principally doing away with heavy unwatering costs.

PERSONAL.

E. A. Austin, mining engineer, Flat City, Alaska, is now in Jarbidge, Nev.

Mark L. Requa, mining engineer, San Francisco, has recently returned from Alaska.

W. D. Abel is now superintendent of the Three R. Mining & Milling Co., Patagonia, Ariz.

P. S. Gray has joined the engineering force of the Winona mine in the Michigan copper country.

T. W. Duncan, San Francisco, is in Deadwood, S. D., examining properties for English capitalists.

J. S. Coupal, mining engineer, Boston, is on his way to Peru, where he will examine gold properties.

Sherman B. Eaton, mining engineer, is engaged in magnetic survey work in the Lake Superior country.

C. F. Williamson, former mining engineer with the Cañanea Con. Copper Co., Mexico, is now in Reno, Nev.

J. L. Head, mining engineer, recently of Flat River, Mo., is now with the Calumet & Arizona Co., Warren, Ariz.

H. B. Barling, mining engineer, New York, has returned from a professional trip to several of the western states.

Howard D. Smith, mining engineer, San Francisco, has returned recently from a trip to New York and London.

Edwin R. Eaton, mining engineer, New York, is installing a mill on a manganese property at Sugar Grove, Va.

Alden H. Brown, mining engineer, 115 Broadway, New York, will leave shortly for Russia on mining investigation.

W. H. Staver, mining engineer recently in Ophir, Colo., has moved his offices from Lynchburg, Va., to Washington, D. C.

Wilson W. Hughes is now superintendent of the Monitor Belmont Mining Co. He was formerly at Guanajuato, Mexico.

A. J. Fasbinder, a construction engineer formerly in Tampico, Mexico, is now at Homestead, Pa., with the Carnegie Steel Co.

Elmer E. Bray, mine operator with headquarters in Los Angeles, is in New York City in the interest of western properties.

R. E. Cranston, mining engineer, San Francisco, has been appointed consulting engineer for the Mining Associates, Ltd., Salida, Colo.

Ralph Meyers, mining engineer, Philadelphia, is making an examination in the Porcupine district, Ontario, for New York interests.

Thomas Stroup, formerly in the engineering department of the Tennessee Copper Co., is now with the Utah Copper Co., Salt Lake City.

Frederick Hellman, consulting mining engineer, Chuquicamata, Chile, has been appointed consulting engineer for the Guggenheim interests.

A. T. Sweet of the class of 1916 of the Michigan College of Mines has been appointed instructor in the metallurgical department of that college.

Hector F. Escardo and William Bull, mining engineers Peru, are in this country and have been investigating method in the Butte district, Mont.

H. J. Kroll, mining engineer, accompanied by his father, F. W. Kroll, is making an auto trip from Houghton, Mich., to Lordsburg, N. M., where his brother, F. A. Kroll, is chief

engineer for the Eighty-Five mine. Mr. Kroll will take up engineering work.

C. H. MacDowell, vice-president of the Mineral Products Corporation, Marysvale, Utah, has been inspecting the properties and is now in Salt Lake City.

L. O. Howard, former superintendent of the Old Dominion smelter, Globe, Ariz., is now superintendent of the International Smelting Co.'s smelter at Miami, Ariz.

Joseph Jensen, formerly a mineral inspector in the service of the U. S. General Land Office, is now assistant professor of mining at Carnegie Institute, Pittsburgh, Pa.

V. V. Kelsey, engineer and geologist for the Clinchfield railroad, Johnson City, Tenn., was in charge of the railroad's mineral exhibit at the chemical exposition in New York City.

Kirby Thomas, mining engineer, New York, and R. S. Knappen of the Columbia University have concluded an investigation of manganese deposits in the Santiago region of Cuba.

J. William Knight, recently appointed general manager of Rico Wellington property at Rico, Colo., has recently been visiting the mine and has returned to his headquarters in Salt Lake City.

Arthur K. Adams, formerly mining geologist for the Mascot Copper Co., Dos Cabezas, Ariz., has left for Chile, where he has accepted a similar position with the Andes Copper Co.

Walter A. Barrows, Jr., consulting metallurgical engineer, Brainerd, Minn., has been elected president and general manager of the Thomas Iron Co., Easton, Pa., to succeed Ralph H. Sweetser.

A. E. Carlton, president of the Cresson Con. Gold Mining Co., Cripple Creek, Colo., and affiliated with many other companies of the district, has been appointed a trustee of the Colorado School of Mines.

M. A. Rowan, mining engineer for the coal properties of the Chicago & Eastern railroad, is temporarily located at Clinton, Ind., where he is engaged in opening the old Klon-dyke shaft in the No. 4 vein. He is also preparing to sink a shaft west of it to the No. 5 vein.

W. B. Milliken, who recently returned to Denver, Colo., from Nicaragua, Central America, has opened an office in McPhee building, that city, as metallurgist and mining engineer. Mr. Milliken and H. E. Fredericks, Denver, own the Linda Ventura mine, some distance interior from Bluefields, Central America.

A. T. Holman, formerly superintendent of the Vindicator and Golden Cycle mines, Cripple Creek district, Colorado, goes to Nicaragua to become superintendent of the Linda Ventura mine, out from Bluefields; and Geo. F. Bridger, formerly at Guanajuato, Mexico, goes to the same property as mill superintendent. The Linda Ventura is owned by W. B. Milliken and H. E. Fredericks of Denver.

OBITUARY.

Will A. Childs, for many years superintendent of the Hecla & Torch Lake railroad, which carries the rock from the mines at Calumet to the mills at Lake Linden, died at Calumet, Mich., Sept. 26 after an illness of over a year. Mr. Childs was born at Constable, N. Y., Oct. 14, 1844, and after a 3-years' service in the Union army, from which he was discharged with the brevet of captain, and a year's attendance for a business course at the old Detroit University, he entered the employ of the Calumet & Hecla in 1866 and consequently was in its service for a little over 50 years, being the second oldest in its force and a recipient of a gold medal in July for his long, able, and faithful performance of his duties. He was Judge of the Probate Court 1872-1880, for 6

years captain of the Calumet Light Guard, and a director of the Merchants & Miners' bank since 1874.

Henry M. Mosher, a well known lease operator in the district surrounding Idaho Springs, Colo., died in that city on Sept. 17, 1916. He was born in Brazil in 1887 and came to Colorado in 1907, where he first located at Central City and later Idaho Springs. The principal property which he operated was the Lake mine, which in a little over 2 years produced something over a half million dollars.

William G. Ramsey, vice-president of the du Pont Powder Co. and chief engineer of its construction department, died Sept. 28 after a brief illness of pneumonia. Major Ramsay built many explosive factories throughout the country and recently was engaged in the construction of a plant in Montana, which will be named Ramsay, in his memory. He was about 55 years of age and was prominent in the business and in military interests in Delaware. During the Spanish-American war, he served as a major in the United States army. He was keenly interested and held various offices in the Delaware national guard and was prominent in various rod and gun clubs.

SCHOOLS AND SOCIETIES.

Exposition of Chemical Industries.—The Second National Exposition of Chemical Industries was held at the Grand Central Palace, New York City, last week. The feature of the exposition was the unusually large number and variety of the exhibits. Among the exhibitors were the following: Hardinge Conical Mill Co., Kelley Filter Press Co., Eimer & Amend, the Dorr Co., Sweetland Filter Press Co., Abbe Engineering Co., Foote Mineral Co., Huff Electrostatic Separating Co., Mine and Smelter Supply Co., Raritan Copper Works, Roessler & Hasslacher Chemical Co., Ruggles-Coles Engineering Co., and the Westinghouse interests. The United States Bureau of Mines was also well represented. A series of moving pictures was presented which showed how the raw products are produced, how iron ore is mined, the process of zinc mining, milling and smelting and the mining and extraction of radium.

NEW PUBLICATIONS.

Triangulation and Primary Traverses in the Various States. Washington, D. C., U. S. Geological Survey. Bulletins.

Separate bulletins for each state and in some cases groups of states are now being gotten out by the U. S. G. S. They contain the location and necessary survey data with respect to U. S. G. S. triangulation stations.

Mica in 1915. By Waldemar T. Schaller. Washington, D. C., U. S. Geological Survey. Mineral Resources of U. S. II:21; pp. 13.

The condition of the industry during the year, production, properties of mica, occurrence, uses, prices and imports during the year are considered under separate headings for the United States. Briefs are given on the foreign mica industry in Canada, Brazil, Korea, China and India.

West Virginia Geological Survey County Reports, 1916. By Charles E. Krebs, D. D. Teets, Jr., and I. C. White. Wheeling, W. Va., State Geological Survey. Report 1916; pp. 778; illustrated.

This is the usual annual report which has been published for the last several years. A complete set of maps is included with the report, there being separate geological and topographical maps for both of the counties reviewed in the report. The entire area of Raleigh county and western portions of Mercer and Summers counties are in the area described. Part I is on history and physiography of the dis-

trict; Part II, geology which is mostly stratigraphy of the coal and other formations; Part III, mineral resources which are principally prospecting for oil and gas and the production of coal; and, Part IV, paleontology.

Mineralogic Notes. By Waldemar T. Schaller. Washington, D. C., U. S. Geological Survey. Bulletin 610; pp. 164; illustrated.

For the greater part the information herein contained is of a highly theoretical nature. The contents were assembled from the results of independent research by the author the work having been confined to uncommon minerals of no economic importance but of considerable importance to the crystallographer and mineralogist.

Sensitiveness to Detonation of Trinitrotoluene and Tetranitromethylanilin. By Guy B. Taylor and Willard C. Cope. Washington, D. C., U. S. Bureau of Mines. Technical Paper 145; pp. 13.

The investigations of these explosives were carried on with respect to their use in blasting caps to supersede the long used fulminate of mercury. The text discusses the nature and property of these explosives and describes both the results and methods used for testing the explosives.

Triangulation and Primary Traverse in Texas. By R. B. Marshall. Washington, D. C., U. S. Geological Survey. Bulletin 644-P; pp. 77.

Data is given on the triangulation stations established from 1913 to 1915. The information is given in tabulated form, there being a separate table for the stations in each quadrangle in the state. The azimuth and back-azimuth or latitude and longitude are given, as also are distances. The different quadrangles are arranged according to counties and only as much descriptive matter is contained in the bulletin as is necessary for locating the triangulation station.

Upper Ordovician Formations in Ontario and Quebec. By A. F. Foerste. Ottawa, Ont., Canada Geological Survey. Memoir 83; pp. 279.

In going over the formation of this era complete descriptions are given of the various formations as noted at their horizons in different localities. Though the work is of little direct economic importance it is of the greatest importance as regards the studying and nature of formations and further interest of value in this memoir is that it has aided greatly in correlating formations in other districts as to their geologic succession.

Report on the Pipe-Line Transportation of Petroleum. Washington, D. C., Federal Trade Commission. Report; pp. 467; illustrated.

In accordance with a resolution of the U. S. Senate directing that an investigation be made into Oklahoma oil prices, transported by interstate lines, this report was written. In carrying out this work most of the lines in the district were reported on as regards the cost of construction and method of the same in detail for each line separately, also the cost and method of organization and operation. Details as regards the earning power of the different lines are given in reviewing the operations and finances of the various companies operating in the district.

Mineral Resources of Alaska. By Alfred H. Brooks and others. Washington, D. C., U. S. Geological Survey. Bulletin 642; pp. 279; illustrated.

This report is on investigations made during 1915 and reviews for the greater part progress made by operating, producing and prospecting companies. Different sections are covered by different authors, but the text of each report is similar in nature and each contains a geographic map of the area covered. Besides reviewing production and operations of different districts an account is given of the coal-land leasing laws as well as a reprint of the exact laws. Water power investigations made in southeastern Alaska during the year are also covered in a separate chapter and a complete index of the entire bulletin is included.

TRADE PUBLICATIONS.

Moulded Electrical Insulations and Sundry Composition Goods. Dickinson Mfg. Co., Springfield, Mass. Catalog No. 7; pp. 22; illustrated.

Different forms of electrical insulating devices of different compositions are listed. Brief descriptions are also given and accompanied with illustrations.

Tools for the Builder and Mechanic. L. S. Starrett Co., Athol, Mass. Catalog No. 21; pp. 336; illustrated.

In general the catalog needs but little explanation, as what is included under measuring instruments for the mechanic is so well known. The line of tools contained is very complete and accompanied with a good index. Each tool considered is illustrated, briefly described and the prices given.

The Campbell System of Magnetic Separation. Zinc Concentrating Co., Boston. Booklet; pp. 8; illustrated.

This system of magnetic separation is stated as being of special value in the treating of zinc, iron-sulphide ores and table middlings. In the form of an article the system is briefly described in its different departments and specific data on results obtained through its use in the field are given, while the concluding pages review operating costs of the system.

Brass, Lead, Tin and Copper-Lined Pipes and Fittings. United Lined Tube & Valve Co., Boston, Mass. Booklet; pp. 24; illustrated.

The construction, description and prices of different kinds of pipe and fittings, manufactured by the company, are given, with sectional views where necessary to show the construction of the equipment. Acid-proof valves, pipe, etc., are spoken of, with particular reference to acid mine waters, leaching plant solutions, etc.

Testing Machines. Tinius Olsen Testing Machine Co., Philadelphia, Pa. Booklet; pp. 31; illustrated.

Illustrations are given of the machines made by this company for the testing of materials, principally structural, to ascertain their strength and other physical properties. Machines for the testing of different properties of concrete, steel, wood, etc., are included. An illustration is given of each machine and is accompanied with a brief description on the use and in what sizes the particular machine may be obtained.

Cast Iron Pipe. Central Foundry Co., New York. Catalog and Booklet; pp. 24 and 14; illustrated.

The catalog is practically confined entirely to illustrations, though some brief descriptions are given as well as complete tables of details for each class of pipe and style of pipe-fitting, such as bends, elbows, tees and crosses, etc. The line of pipe and pipe-fitting, however, is complete. The booklet, "Universal Pipe in Service," gives various views and short descriptions of both mine, plant and various other installations using the company's pipe.

Oxy-Acetylene Welding and Cutting Equipment. The Turner Brass Works, Sycamore, Ill. Catalog W. 303; pp. 16; illustrated.

Besides the catalogued equipment contained a concise discussion is given regarding this company's particular equipment and oxy-acetylene equipment in general. Tanks, torches, burner tips, regulators, gauges and complete outfits in wooden cases are included in the catalog section. In the concluding pages illustrations are shown of difficult welding jobs which may be easily accomplished by oxy-acetylene welding.

Boiler Tube Cleaners. The Lagonda Mfg. Co., Springfield, Ohio. Catalog L-9; pp. 36; illustrated.

Ordinarily one page is confined to the illustration and description of the construction, operation and uses of the different kinds of cleaners and sundry other equipment. The

first few pages, as a preface, takes up the subject of boiler-tube practice in a general way, including a description of the Lagonda cutter-head. Water-driven cleaners for boilers and turbines are described in several different styles, as also are types driven by compressed air or steam. Besides this several types of special cleaners and other miscellaneous equipment and repair parts are given consideration.

Texaco Crater Compound. The Texas Co., New York. Booklet; pp. 31; illustrated.

This booklet tells the story of the Texaco Crater compound for lubricating and it is stated that the compound is a straight heavy lubricant containing no filter substances. The nature and features of the oil and what class of service it is most adaptable to is brought out. It is claimed that the lubricant may be used as a preservative for hoisting and other wire ropes as well as a lubricant of machinery, and practical applications of its use in the field are described briefly for different cases. The importance of lubricating wire rope is spoken of and among other subheads are "How Crater Prevents Wear" and "How Crater Prevents Corrosion."

INDUSTRIAL AND TRADE NOTES.

Carney Hartley, M. E., 318 Colorado building, Denver, recently took over the intermountain agency for Julius Blum & Co., New York, dealers in steel, bronze, copper, brass, nickel and other metals, for shops and mines. This line includes drill steel.

The Denver Rock Drill Mfg. Co., Denver, has built a 100 by 125-ft. addition to its shops in which new machinery and equipment are being installed. This additional floor space and new shop equipment will result in increasing the company's drill-making capacity between 40 and 50%.

The Denver Quartz Mill & Crusher Co., Colorado building, Denver, reports many sales and installations of its mills in all sections of the mining country. Jos. S. Bartley, manager of the company, states that 1916 is the best year the company has experienced and he anticipates a still better season for 1917.

The Mine & Smelter Supply Co., Denver, recently sold two 6 by 4½-ft. Marcy ball mills to the Missouri Cobalt Co., Frederickton, Mo., and has an order from Allis-Chalmers Mfg. Co. for 30 No. 6 Witley concentrating tables for export. Among the sales of Marcy mills made this year were 15 of these machines to the Braden Copper Co., for its mills in Chile, S. A.

The Vasco concentrating mill, built and equipped at Stevens camp, Boulder county, Colorado, by Hendrie & Bolthoff Mfg. & Supply Co., Denver, has operated 60 days and demonstrated its adaptability to treating tungsten ores. It is so arranged that the flow-sheet may be altered as required for different grades of ore. The fine concentrates are made by 6 Card tables, manufactured by this company.

Morse Bros. Machinery & Supply Co., Denver, has shipped from its yards and warehouses over 200 cars of mining machinery since January 1, 1916. These shipments have been distributed to all the mining states and to other countries. A recent shipment outside of the United States, consisted of a McDougall roaster to Cuba. All this is evidence of the activity in mining and the consequent demand for equipment.

The Western Electric Co. has moved its offices and show rooms in Buffalo from 98 Terrace to 709-711 Main street. The new location with two large show windows fronting on as many streets affords splendid display facilities. The full line of Western Electric quality products will be carried and the high standard of service that marked the company's business at the old office will be strictly maintained at the new. J. W. Tabb is the manager.

Late News From the World's Mining Camps

Editorial and Special Correspondence.

ALASKA.

Juneau.

According to E. Renfer and Charles Renfer, who have been going over the Broad Pass country, they have recently made a good strike on a quartz vein after spending several months in the district. The strike is along Ohio creek, and of such proportion that it will be worked on a very large scale as soon as the railroad is constructed. The location is about 7 miles from the railroad and it will be a simple matter to haul freight from the railroad. The ledges are exposed for hundreds of feet and contain gold, silver and lead.

Miller & Co., who have been working in the district for a distance of 200 ft., have been able to trace the same ledge which appears on the surface. Representatives of the Rockefeller family are in the district now, investigating some property which is owned by Dr. J. H. Callie, of the coast. There are about 20 men in the district now, prospecting and doing assessment work.

Valdez.

The latest assays from every face in the Granite Co.'s property are good and show increases, according to reports of President B. F. Millard. Assays show on the "hoist level" 10 ins. of \$71.10 ore, 8 ins. of \$295.58, and 11 ins. of \$166.19. Some of the richest ore ever found in the mine is now in the face of the hoist level. This also holds good on the 210 level. We are getting high grade ore there, and have had a continuous pay shoot for 250 ft. On the 350 level we are getting \$4 ore. Starting at 50 cts., it is getting better all the time as we go in, and I believe when we get over to catch the shoot of rich ore on the 210 level we will have it as good on the 350. The average of the 210 level for month of August was \$16, and the vein averages 38 ins. wide. The hoist level on the granite side is showing up rich. We followed the fault on the slate end of 350 level 80 ft. to the right and picked up the vein with milling values. This gives us pay ore on three levels and no doubt it continues from one level to another. I still hold that our best ore will be found going into the granite and perhaps on the upper side of the dike. We have had trouble getting good miners and had to fill up with black men, but after sorting out we have a fair crew.

Developments at the Black Diamond group are encouraging and plans are now being made to operate through the winter. The Black Diamond claims cover two veins. One of them is the same that runs through the Three-in-One. The other is a parallel vein several hundred feet away. Both of the veins have been traced the full length of the claims. The property has been located for several years, and considerable development work has been done. This work has demonstrated that the ore in the lead crossing the Three-in-One carries the same values on the Black Diamond as in the former property. On the parallel vein, where the work is at present being done, it has been demonstrated that this vein carries ore equally as rich as the other.

The development work now in progress is in charge of Frank Kempfer and he expects to have the property sufficiently developed by spring to warrant the erection of a mill.

ARIZONA.

Oatman.

Development of the past few weeks by the Tom Reed Mining Co. point to the possible development of a second mine equal to its main or Ben Harrison mine, which has al-

ready enabled the company to pay almost \$3,000,000 in dividends. The company owns 477 acres, and its main mine covers about two claims. Some three-quarters of a mile to the southeast of its main shaft, on the Black Eagle claim, an exploration shaft was put down 600 ft. and a big vein of fine mill ore opened on several levels. Another shaft was then started some 600 ft. to the northwest of this shaft, and at 400 ft. tapped the vein, and at this time the ore shoot is at least 18 ft. in width, showing average values of \$14.67 in free-milling gold. Exploration work has given results which cause the officials to believe that the ore shoot is continuous from the new shaft, which is on the Aztec claim, to the extreme southeastern limits of the Black Eagle, a distance of several hundred feet. Indications seem to favor this section of the lode upon which Tom Reed is located, developing into a mine of importance equal to the old main workings. In the main workings ore is being stoped on several levels, and on the 1400 drifting operations are entering what appears to be the downward continuation of the main ore shoot worked on the upper levels.

Big Jim is now upraising from the 400 level in order to ascertain just how high the ore shoot first opened on that level extends upward. Splendid ore is being developed.

Nellie, in the Black Range section, has just cut a station at the 350 level, and has opened a body of the typical green. adularia-quartz which is the mineral carrier in the Oatman ores. The development has caused much excitement, although not enough work has been done to prove the importance of the find.

The Adams shaft in the same section is now down 275 ft., and a change of formation has been encountered which is significant. The company expects to enlarge its working force within a few days. No lateral work will be done until a depth of 400 ft. is attained.

The Gold Dust, in a winze from its second level, 800 ft. to the northwest of the shaft, has opened an ore body 14 ft. in width, and averaging \$12. The company has 50,000 tons of pay ore blocked out. The old Orion mill, on this property, is the scene of experiments with a new amalgamating device which gives centrifugal agitation of pulp and amalgam, and it is claimed that a very high saving is being effected, and that treatment cost is very low. If the test continues successful, the mill will be equipped for a large production.

The Gold Ore Co. is said to again be considering the erection of a 30-ton mill, and its officials are manifesting much interest in the experiments at the Gold Dust property.

The Lucky Boy Co. is preparing to resume operations. The Esperanza will resume shortly, as will also the Lazy Boy.

The mill of the United Eastern is now more than 60% completed, and is being rushed by a big force of workmen. Before the end of the year the United Eastern should enter the productive list.

The Gold Range Co. has negotiations for refinancing and the resumption of operations well under way.

United Northern, at a depth of 500 ft., is entering formation which causes Engineer Goldsworthy to anticipate important news within a few days. It is highly oxidized, heavily impregnated with hematites and carries good values.

Oatman United plans to resume extensive operations within 30 days. Others which will soon probably be operating again are the Lucky Sam, Arizona Gold Star, Times and Telluride.

Pictured Rock at a depth of 250 ft. appears to be driving into the hanging wall of its vein. Steady and favorable operations are in progress on the North Star, Oatman Amalgamated, Sun Dial, Black Range, Jerome Oatman, Oatman

Gold Mining & Milling, Arizona Central, Chicago Syndicate, Wrigley Exploration, Oatman Belle, and a number of others.

Tuscon.

Oro Belle directors held a meeting last week in Michigan and called a meeting of the stockholders here Oct. 20, to ratify the agreement made recently with John Hays Hammond's representatives whereby Mr. Hammond and his associates will develop the mine on an optional basis. There are yet some details to be arranged and the terms will not be made public for a few days. A full meeting of the board of directors was present: H. W. Fesing, Prof. A. E. Seaman, and Wm. Duffney—all of Houghton; and Pres. W. B. Andrews and R. J. Andrews of Duluth. T. A. Merritt of Duluth, one of the original and largest stockholders, also attended the meeting. Mr. Hammond's proposition will be probably accepted. Wm. Duffney, who was of Boton, was elected to fill the vacancy caused by death of Benj. F. Chynoweth of Houghton.

CALIFORNIA.

Goldstone.

The Goldstone district is fairly launched on an era of active developments. Five companies and 15 sets of lessees are working, and fully 30 independent miners are prospecting proven ground. A large number of prospectors are active. The new custom mill, owned by Bullinger & Daluge, has been placed in commission and is handling good grade quartz.

The Goldstone Mining Co. has arranged for the immediate installation of a hoist and power drills, and plans to sink the shaft 700 ft. From this level a series of crosscuts will be extended to tap the various veins disclosed near surface. New York capital is interested.

H. L. Cowles, representing Chicago capital, has taken an option on several properties and expects to close an important deal shortly. The United Goldstone Mining Co. has arranged for early work on its 23 claims. Several veins outcrop and some high-grade ore is in evidence.

Beaumont.

A long-term lease has been taken on a group of magnesite claims near Winchester by the W. Wells Co., 101 Broad street, New York. Lessees agree to mine not less than 1500 tons of ore monthly. If desirable, the property may be purchased outright for a specified sum. A large tonnage of good ore is on the dumps, and extensive reserves are indicated underground.

Jackson.

The strike of the miners in Amador county continues in force, but indications are favorable for the eventual triumph of the companies. Operations have been resumed with a full force at the Plymouth Con., near Plymouth, the employes asserting they were never in favor of a walkout, and are contented with wages and hours. At several other properties some work is going on and the pumps are kept in constant commission. A few acts of violence have been reported, but the authorities appear to have the situation under strong control and agitators have been promptly quelled.

Masonic.

A good output continues to be made from the Serita mine, controlled by the Stall interests. The enlarged Pittsburg-Liberty mill is running steadily on ore from the main Serita levels. It is reported that some good ore has been recently exposed in the Pittsburg-Liberty mine. A number of outside properties are receiving attention. Considerable Reno capital is interested.

Williams.

Quicksilver mining is very active west of this place, with several good producers receiving attention. At the Boggus mine, controlled by J. W. Boggus and associates, ore of excellent grade has been opened and the furnace is now fired with oil instead of wood, effecting a monthly saving of \$100.

Placerville.

The extensive chrome deposits at Negro Hill have been acquired by the Noble Electric Steel Co. of San Francisco, and preparations made for the daily shipment of 30 tons per

day to eastern points. The smelter at Heroult is handling all the chrome ore it can accommodate at present. The company is prospecting numerous manganese deposits and producing considerable ferro-manganese by the electric furnace method.

Grass Valley.

At the late meeting of Union Hill stockholders all officers were re-elected with the exception of G. S. Johnson, who was succeeded by W. H. Hamilton. Ore extracted from the scheelite deposits is paying all operating costs, and 10 tons are held for better prices. Considerable high-grade tungsten has been recently exposed. The gold veins are being steadily followed and as soon as the shaft is sent 400 ft. deeper comprehensive lateral work will be undertaken at this point.

Columbia.

Rich gravel has been encountered in the Ranch mine, acquired last spring by the Springfield Tunnel & Development Co. Considerable coarse gold is present and the drift is apparently on the rim of an extensive and wide channel. The main tunnel on the Springfield group is advancing rapidly and raises and drifts are being extended to open the main gravel deposits. It is stated that late work has demonstrated the success of the enterprise beyond all question.

Alleghany.

Work was resumed in the Rainbow Extension last week by a new company which has taken a bond and lease on the ground. Power drills will be provided and an effort made to intersect extensions of rich shoots formerly worked in the adjoining Rainbow and other mines. The property has never been worked to any extent although well located.

Georgetown.

The Georgia Slide Mining Co. has taken over the Beebe and Mulby Point mines and is arranging for extensive work. It is reported the Eureka mine, owned by the Woodside-Eureka Co., will also be operated in conjunction with the Beebe. All the properties contain considerable ore and have been worked extensively. At the Georgia Slide a large amount of development work has been accomplished in the past year and new ground proven. Colorado and California capitalists are chiefly interested. J. C. Ingersoll will have charge of the new operations.

Plymouth.

The Plymouth Con. is installing a powerful electric hoist and expects to have it in commission early this month. The 30-stamp mill is crushing over 340 tons per day, the stamps being aided by rolls and other fine crushing machinery. The product averages around \$5.43. August net earnings were \$22,467.

W. J. Loring, consulting engineer and president of the Plymouth Con., has taken a 3-months' option on the Hardenburg mine, about 2 miles east of Jackson. The mine is well-equipped and is located among some of the best producers on the Mother Lode.

Downieville.

Operations have been resumed at the Gold Bluff-Oxford group after a brief idleness and 45 men are at work. The mill is again operating on ore of good character. The group is controlled by the Cliff Leasing Co. of Salt Lake. Sol Camp is superintendent.

Keeler.

Announcement was made today of a dividend of 2½ cts. per share, declared and paid last week by the Cerro Gordo Mines Co., whose zinc-silver property in Dayo county has within a year become one of the most important producers of the southwest. The history of the past 12 months is one of the most encouraging from a mining standpoint recently written in California. When L. D. Gordon of San Francisco assumed control a year ago, and during 3 months of a lease he had previously obtained, just prior to operations on company account, directed extraction of every available pound of zinc ore. Since that time the company has paid off indebtedness of \$40,000, created a treasury reserve of \$50,000, paid its \$25,000 on the outstanding 1,000,000 shares and paid for improvements costing \$15,000. The latter included an entire electric system to operate hoist and compressor, a warehouse at Keeler and the covering of three tramway terminals. The

gross revenue represented in these items is about \$130,000. The production of zinc and silver continues at the usual rate and the management believes that the dividend rate may easily be maintained.

COLORADO.

Georgetown.

At the Capitol mine, which for years has been worked as a producer of silver, leasers have opened a vug of ore estimated to contain \$100,000. Three weeks ago miners working on a raise 290 ft. from the main tunnel level uncovered a streak of ore 2½ ft. wide, all first-class, which ran 1390.41 ozs. gold. Alongside this is another streak 3 to 4 ft. in width which gave 88.50 ozs. gold.

Telluride.

The Wagner Development & Mining Co., operators of the Alta mines and other groups in Gold King basin, has purchased the Junta 65-stamp mill, including the tramways, etc. Next year after the completion of the new wagon road now in course of making the entire purchase will be moved up to include the Alta mines.

The Ophir Gold Mines & Reduction Co. has filed articles with the county clerk. The holdings of the company are those which Jim Belisle and Newton Sankey have been developing. The directors for the first year are C. M. Goddard, Denver; James M. Belisle and Newton Sankey, Norwood. They have a number of gold-bearing claims above Ophir and also have a vein of molybdenite from which some nice specimens have been taken.

The Tomboy, Smuggler and Liberty Bell mills are making more concentrates from the individual properties than for years.

Manager Smith, of the Highland Mary Mining Co. at Ophir, let a contract for 100 ft. of work on its property at Swamp canon to Mose Hill. The drift they will extend is the one in which they made an excellent strike a week or so ago, and they want to determine the extent of the ore body opened.

At the Black Bear mine they are doing considerable building, enlarging the workshop, putting an addition on the converter house, etc. They will shut down for a month while they enlarge the shaft and get ready for installing a skip to take the place of the bucket now used.

The lmes at Sawpit, being operated by Ouray interests, is showing some good ore. The property is the old Fourth of July claim.

Ophir.

The raise at the Silver Bell has reached the highest or sixth level. Its raise is 2-compartment and the distance between the mill crosscut and the higher level connected is 828 ft. It was run on ore all of the way. There is a mill on the property which could be brought into use. The mill equipment is 50 stamps. Frue vanners and bumping tables, and with the flotation and grinders, the mill would be up to date. The mill crosscut is now in 1800 ft. and may be driven in further—for when work on this level was discontinued it was being pushed south towards a considerably stronger mineral zone than that through which they had previously passed. The Kracaw group upon which the company has a lease lies to the south of the Bell. These have splendid surface indications, and have also been proven at some depth and are considered good claims.

Ouray.

King Bros. & Lovinggood, lessees of the St. Paul property near Red Mountain, have made another good strike on that property, opening up a new ore shoot 15 by 18 ft. The discovery was made about 25 ft. from the body opened up early in the spring, and appears to be even better than the old one, which has netted an average of something over \$800 per car. Since the first of the year they have shipped about 50 cars of ore running as above stated. They are now working 18 men and may increase the force.

The Gold Crown Mining Co. has decided to push its mill to completion. The company has acquired some good min-

ing property and it is all situated just below the city, convenient to the railroad and its mill. Completion of the mill is the key to the successful operation of the property.

A recent good find of quartz several inches wide has been made at the Governor. Alongside the quartz are several inches of talc that pans \$5 per lb. The extent of the ore bodies are as yet unknown.

Cripple Creek.

Vindicator's flotation plant it is said will be ready for operation by Oct. 15. It is now under construction at the old La Bella buildings and new ones erected for the purpose below the Golden Cycle mine dump. During the past year the company has made numerous tests with Vindicator and Golden Cycle ores, and these tests have warranted the construction of the new plant. The mill will have an initial capacity of from 350 to 500 tons and it is the plan of the company to increase this capacity from time to time until 1500 tons daily, the ultimate capacity, is reached. In the mines of the company there are reserves of low grade ranging from \$5 to \$8 a ton available, while the ore house dumps are estimated to contain in excess of 3,000,000 tons of waste ranging from \$2 to \$3. This ore will be treated. Ore conditions in the main Vindicator shaft are said to be in better condition than for a long period past, and in places the ore body at the 16th level is reported to be 50 ft. wide and averaging \$30 a ton.

A raise from the 1st level at the War Eagle Con. has disclosed ore and a new rock house is being constructed at the War Eagle shaft. The raise carried up to within 75 ft. from surface has entered a new flat. Supt. Kissel has opened the vein for about 20 ft., and is breaking ore about 3½ ft. thick. The values are 1 oz. gold. The more important development is the cutting of the Josephine vein by a cross-cut carried 85 ft. east of the new 3-compartment shaft on the Happy Year claim, from the first level station at a depth of 125 ft. from surface. The vein as exposed measures 5½ ft. Drifting will now be started, and from past developments along this dike it is practically assured that other ore shoots will be disclosed within the boundaries of the company. Rapid progress is being made in the Happy Year shaft and a depth of 225 ft. has been attained. This shaft, the main working shaft for the War Eagle group, is to be continued down to the 500 level and from the present indications the work will be accomplished before the close of the year.

Breckenridge.

The output of the four gold dredges in Breckenridge district for 1915 was \$700,000, and it is estimated by H. J. Reiling, president of the French Gulch Dredging Co., that the 1916 production will considerably exceed that figure. The French Gulch, which operates a dredge with 6-cu. ft. buckets, is handling 70,000 cu. yds. per month, recovering about 27 cts. per yard. The record of a recent weekly cleanup showed \$5007. The dredge operates to a depth of 43 ft. on French creek, taking up about 1 ft. of the bedrock. The Tonopah Placers Co. operates one dredge on French gulch, down stream from that of French Gulch Co., of about 70,000 yds. capacity; also, a dredge on the Blue river, and one on Swan creek. The last two named have capacities of 150,000 yds. each per month. It is understood the grounds being dredged on the Blue and Swan run about 15 cts. Manager Hopkins is in charge of the Tonopah Placers Co. dredges.

Red Cliff.

Iron Mask mine, at Gilman, near Red Cliff, being operated by Empire Zinc Co., is producing about 150 tons per day of zinc ore. This is treated at the company's mill, close to Red Cliff. The process is one of separating the zinc from the iron by magnetic machines, producing about 50 tons per day of zinc concentrates.

GEORGIA.

Dahlonega.

The Crown Mountain Co. is pushing work rapidly and will soon have 20 stamps running on ore from the Wallace vein, and others that have been opened. They are using jackhammer drills, and two drills break more ground than the

day crew can muck, and it requires a night crew to clean up the muck, to be ready for the day crew in the morning. Two drills working part of the time recently drilled 37 holes from 4 to 6 ft. deep, and better results are expected later as the drills are new at this mine. This part of the work is under the personal supervision of Mr. Henry Reinnier.

The Toledo mill is running 10 stamps and the tube mill regularly and expects soon to have enough ore to supply 20 stamps from the various veins opened and put in working shape during the past few months.

IDAHO.

Wallace.

The Caledonia Mining Co., which owns and operates the Caledonia mine, near Wardner, and is treating its product in a unit of the Bunker Hill & Sullivan mill at Kellogg, on the 5th paid a 3-ct. dividend. This makes for the current year \$755,340, and will increase the grand total to \$1,638,181. The net earnings for August were approximately \$100,000, as compared with \$90,000 in July, according to President Stanley A. Easton, who states also that there are no new developments of consequence in the Keating tunnel level, where search is being made for the ore body that faulted several months ago. The quest for the deposit still is being continued, however, and the belief prevails that the effort will be crowned with success.

Diamond drilling has located an important deposit in the Copper King mine, near Mullan, according to H. W. Ingalls, secretary of the Copper King Co., who states that the drill has penetrated 17 ft. of ore, part of which is high grade, and the remainder concentrating material, the shoot carrying from 5 to 10% lead and fair copper values. The drilling is being done from the face of the west drift in the lower crosscut tunnel, about 1400 ft. below the outcrop and about 480 ft. of ground had been penetrated before the ore was encountered. It is believed to be the same shoot that has been opened in the upper workings, and the company plans to explore it both from the main tunnel and from the drift from which the diamond drilling has been done.

The Constitution Mining Co., which owns and is operating the Constitution mine, in the Pine Creek district, will expend about \$20,000 in new equipment, to be installed and ready for service not later than Jan. 1, according to Judge George Turner, president of the company. "Contracts for the construction and machinery for a mill of 100 tons daily capacity have been let and we expect to have the plant in operation by Jan. 1," said Judge Turner. "We had plans prepared by Supt. Ziegler of the Success mill some time ago, and we finally decided to put the concentrator in operation as soon as possible, so as to take advantage of the 3 months of sleighing in marketing our product. For a time we favored postponing the construction of the mill until railroad transportation was absolutely assured, but we concluded that the operation of another mill might hasten the construction of a railroad and that in any event we should not be long without railroad facilities. Meanwhile we shall do very well for the winter season with sleighs."

The Sunshine group, in the Beaver creek district, rapidly is developing into one of the most promising properties in the region, according to Dr. E. G. Ellis of Missoula, Mont., treasurer of the Sunshine Co. "Plans are under consideration for consolidating the holdings of the Sunshine and other Beaver creek companies, and if the deal is consummated the amalgamated concern will have one of the finest groups of partly developed properties in the Coeur d'Alenes," said Dr. Ellis. "The consolidation will not include the Ray-Jefferson Co., despite rumors to this effect, but a number of the men interested are among those who made the Ray-Jefferson what it is, and they no doubt will duplicate the performance with the proposed new merger. Our development consists of a crosscut tunnel, the bore to be run an estimated distance of 900 ft. to cut the ore body already developed in the Toughnut claim at an additional depth of about 450 ft., which will give over 800 ft. depth on our present ore body. We already have run over 80 ft., all in high grade milling

ore from 4 to 8 ft. wide, and in places we have cut into high grade shipping ore. We have proved our ore shoot over 200 ft. long. We have contracted for an Ingersoll-Rand drilling equipment and air compressor, part of which already is on the ground."

Boise.

Robert N. Bell, state mine inspector, is authority for the statement that the richest gold quartz strike in the history of the state was made recently in an abandoned mine at Atlanta, 80 miles from Boise, a district that was one of the western Eldorados in the early days, but which has been dormant for the last 20 years, the deposits presumably having been exhausted. The camp is credited with production running into the millions of dollars in free milling gold, but at depth the formation became refractory and the different holdings were deserted. The new discovery, comprising a pay streak from 2 to 10 ins. wide, has been opened for 280 ft., giving a vertical depth of 180 ft., in a crosscut 60 ft. above the main working level of one of the old properties. The high grade stringer assays \$2000 a ton, and careful sampling across a face of 2 to 3 ft. wide is said to show average values of \$200 to \$500, while picked specimens carry bands of native gold fully half an inch thick. The discovery was made in the deepest level of the Atlanta camp, being about 1000 ft. below the surface. The ore now is being sacked for shipment, and in the next month it is said that a consignment will be forwarded to the smelters that will compare favorably with some of the output of other bonanza camps of the west.

LAKE SUPERIOR.

COPPER.

Houghton.

Copper Range has taken option on Secs. 10, 11, 12, 13, 14 and the northwest and southeast quarters of Sec. 15, which are located in two rows, the first sections above the last three, lying on an east and west line Secs. 12 and 13, as the eastern ends. The tract is 3 miles long from east to west and 2 from north to south, and its eastern end is directly under the eastern end of the Globe. Some work has been done on this before, on the Globe to the north and the Challenge to the south, but in neither case was there any attempt to make a cross-section. There is considerable overburden in some places, but there are many places where there is but little, and quite a large number where there is none. The county road crosses a conglomerate that is almost completely exposed.

At the 250 ft. level in order to crosscut about 40 ft. or so to the two sandstones and the intervening shale or slate so as to be able with that from the 50 ft. level to get out rock for the experimental mill, where flotation on a commercial scale of native copper will be carried on for the first time in history and where also it will be used as a commercial process in the Lake Superior copper country. From the successful experiments that have been made by Prof. Chapman at the metallurgical department laboratory at the Michigan College of Mines it is considered here that the process will work out very satisfactory on a large scale. It will be some time before the mill will be ready for the rock.

North lake, about 400 ft. southeast of its shaft in crosscut, has just crossed a lode 25 ft. wide that has a good deal of copper in small particles, but not of merchantable grades. The crosscut will be continued, as there is at least one more lode passed through in the diamond drill explorations that gave a promising core. The northwestern drift which is seeking the North lodes of the South Lake, is progressing; it still has quite a way to go.

Isle Royale's dividends of \$1 quarterly and \$1 extra confirm the belief that at last it is on the road to success. Before any great depression in the price of metal takes place, the development will be so great that construction costs will be of the past, and the reserves will be so large that with 6000 to 8000 tons daily, this mine will give substantial profits even with 12-ct. copper. After No. 7 and No. 1 have been fully equipped and beginning to get a fair sized production, it is

likely that another shaft will be sunk, and perhaps after that is in commission there will be still another. It is now certain that the shaft-rockhouse for No. 7 will be constructed of wood and will be similar to that at No. 5, which will be completed in about 2 months. No. 7 will in about 60 days be cut out all the way down to full size. The daily tonnage has decreased very slightly to between 2900 and 3000 tons as compared with the last 3 months of between 3150 and 3000, about 2200 tons being milled at its own mill.

Quincy is keeping up its development at about the same rate. Sinking is proceeding at all three shafts, No. 2 being engaged in cutting its plat at the 76th level, the deepest of the mine, No. 8 is doing the same at the 65th level, and No. 6 is almost down to the 74th. The ground in these lower levels is fully equal to that which has shown such marked improvement in the copper contents, especially in mass. The normal tonnage, which fell off somewhat a while ago owing to the repairs made necessary by air blasts, has been attained again, and about 4000 to 4100 tons will be coming daily for a very long time. As the ground shown at No. 9 shaft had been of too low a grade to be profitably mined, drifts much lower are being carried over from No. 8 to test the values at depth.

Keweenaw has in stock pile 35,000 tons for the mill test that will be given soon. There is also a large amount broken down in the mine ready to be hoisted. All the rock that can be handled by the Ball stamp—200 to 250 tons daily—can be easily supplied, as there is quite a large amount of stoping ground available.

Almeek has good grades of commercial copper in the 75 ft. of drifts that have been so far opened on the Kearsarge lode with a good width. The bonanza fissure, which runs at right angles to the Kearsarge amygdaloid at the No. 2 shaft, containing much copper in the sheet form with an average thickness of about 9 ins., and which contributes about 150,000 tons monthly to the mine's production, disclosed a pathway so profitable with its good contents that it paid all expenses, to the conglomerate.

South Lake is shipping at the rate of 150 tons daily to the Franklin mill. This is a profitable production from which some money will go into the treasury.

Victoria will begin to sink its shaft from the bottom of the skip pit about 30 ft. below the 26th level, to the 27th. The best disclosures in the mine are at the first named level, and it is hoped that the good ground extends down into the 27th.

Calumet & Hecla will very shortly add the second and last unit to its old boiler plant; this only completing this part of the leaching plant as originally planned. The leaching plant is a most complete success, as very few changes have been made and those only of small importance. One-half has been in operation for some time now and the other will not be long into going into commission.

IRON.

Nashauk.

There are four plants for washing siliceous iron ores in this district. Butler Bros. operate one at the Harrison mine. The plant is of steel construction. To a unit there is 1 revolving screen, two 25-ft. log washers, 4 turbos and a number of concentrating tables. The Hawkins mine of the Wisconsin Steel Co. also has a washing plant like the Butler. This is working night and day with a daily production of about 5000 tons of concentrates. All of the ore from the Hawkins pit is treated. At the Crosby mine of the Cleveland-Cliffs Co., another modern plant was constructed during the last year and is seeing its first season of operations. This is a half unit capacity. It has a trommel, a log washer, 2 turbos and 5 single-decked Overstrom concentrating tables. The LaRue Mine of M. A. Hanna & Co. has a washing plant working on a different principle than those used in the other mines. Here what is called the Wetherbee system is used. It plans to simplify the process and do the work now done in the other plants by the turbos and the tables. The plant is working satisfactorily with a capacity of 150,000 tons of concentrates.

Another feature is the large Bucyrus shovel used by Butler Brothers on stripping contracts and described re-

cently in the Mining World. New mines have been developed, which will produce large tonnages during the year. The Mace No. 2 mine of the Longyear-Bennett interests, was stripped last winter and is now shipping. The Kevin, stripped and mined by Butler Bros., shipped its first cargo in September. The Harrison, also mined by Butler Bros., is developing into a good producer.

Ironwood.

At the Woodbery shaft of the Newport mine the work of concreting is going ahead steadily. The shaft is now bottomed to the point originally decided on. The machinery comes slowly, deliveries being held up from lack of material, etc. The company is mining at its usual rate and will have a fair shipment for the year.

MISSOURI-KANSAS.

Joplin, Mo.

In spite of the excellent weather conditions now prevailing in the Joplin field, there is still a lack of water for milling purposes. This, together with the high price of powder and mine supplies, continues to hold down the output of ore to a surprising extent, in view of the prices paid for both zinc and lead ores during the past 3 weeks. Especially noticeable during the week was the strength of lead ore, which brought from \$70 to \$75, which represents a price much above the level being paid for zinc. Naturally ore producers are selling this class of ores very freely, and are depleting their surplus stocks while the price of ores are so high. This high price also helps materially in keeping a very large number of the sheet ground mines going at the present time.

In the West Joplin field there is considerable prospecting. The Old Keller land on West 28th street has been leased to the Tulsa Zinc & Lead Corporation, who has opened up a very good deposit of ore at the 100 level. In addition to the upper level a new shaft is being sunk 165 ft. to open up a run of ore said to exist at that point, in thickness from 30 to 40 ft. During this development the company has started the construction of a mill which is expected to be ready by Oct. 15. Those interested in the property are Jesse A. Harp, Ft. Smith, Ark.; T. F. Moffett, of Joplin, and J. W. Fulker-son and Dr. B. U. Cunningham, of Tulsa, Okla.

On a lease of the Riseling land on West 7th street, the Osceola Lead & Zinc Co. is rapidly completing a new shaft on its lease for which plans have just been drawn for a new 400-ton mill. It is believed that the ground will be opened up sufficiently to supply this tonnage by the time the mill is completed. Stokes & Shoemaker have developed a very rich prospect on a tract of ground southeast of Joplin which shows a 20-ft. face of ore, and so far has been outputting 20% zinc over a custom mill. A new shaft is being sunk to the 180-ft. level, and while this is being done a 150-ton mill will be erected. As a sub-lease, Haggard & Wade Mining Co. has opened up a prospect at the 160 level on the adjoining 10 acres. A short distance west of the old Bumble Bee, Gus James and the Lackey Bros. are sinking a shaft on a sub-lease to open up an ore body which they have developed by sinking of three drill holes. In the same vicinity B. R. Clarke & Co. are completing the erection of a 150-ton mill and have three shafts in good ore.

The Old Saginaw Mining & Leasing Co. has succeeded in draining a 750-acre tract southeast of Joplin. The company has spent much time and money in unwatering this tract. For many years it was a great producer of ores at a shallow level and is now being sub-leased to small producers.

In the Tuckahoe field there has been a revival of activity among the old diggings. On the Sheridan and Adams tract a company of prospectors have reopened the Old Cherokee mine and have been unusually successful in opening up a prospect at the 155 level. The ore is high grade and a good production is now being made with hand jigs.

Immediately north of the Cherokee Mining Co. is a 10-acre lease being opened up by the Gunny-Sack Mining Co. This property was at one time known as the Little Minister and has extensive workings at the shallow level. The new

company is undertaking a prospecting campaign to open up the lower level.

On the Old Pilgrim ground the Three-"J" Mining Co., composed of H. L. Aikens, John Damon, B. F. Neff and Walter Neff of Joplin, are opening up a prospect showing a 9-ft. face of zinc ore. Drifting is being conducted in two directions and the company is taking out some very rich ore.

Carthage, Mo.

Playter Bros. of Joplin, and Steve Chitwood of Carthage, have taken a lease on the old Carthage-Pleasant Valley camp and are drilling out a portion of the ground. The company is trying to find the extension of an old ore deposit worked by previous operators, and will conduct a thorough prospecting campaign upon their lease.

The Osage Mining Co., northeast of Carthage, in which Dr. Chas. Powers of Springfield, J. W. Ellis and Edgar Fugitt of Webb City, is putting down a shaft to the 180 level, in an endeavor to open up an ore deposit which was demonstrated by drilling at this point. The shaft has just entered the ore deposit and the prospect is said to be promising.

MONTANA.

Butte.

J. P. Meyer of St. Louis was in Butte this week. He was recently elected president of the Granite Bi-Metallic Mining Co. at Philipsburg. He succeeds L. M. Rumsey, Jr., of St. Louis. The Granite Bi-Metallic is working steadily and is producing regularly. No big development work has been started yet, Mr. Meyer said:

Retimbering of the Butte Main shaft has been completed and crosscutting will begin at once on the 700 level, the Main Range's lowest, and an old crosscut on that level, which is already in a distance of 200 ft., extended to the side line of the property, a distance of 1200 ft. This work will require about 6 months' time. The 500 and 600 levels are being cleaned and a car of ore of good grade already has been mined, which will be shipped this month. All the surface improvements at the Main Range have been completed, with the exception of a dry, which will accommodate the miners of the Colusa-Leonard Extension in addition to those of the Main Range. At the Colusa-Leonard a Nordberg, a first-motion hoist, is being installed. The old engine house has been dismantled and a new one will be built immediately. Sinking of the Colusa-Leonard shaft to the 1600 will begin as soon as the engine is in place. The present depth of the shaft is 800 ft. The Tuolumne Copper Mining Co. is operating both the Colusa-Leonard and the Butte Main Range, in addition to the Tuolumne mine. At the Tuolumne mining of ore is in progress on the 2200, 2400 and 2600 levels, and the old stopes on the 1200 and 1400 levels also are being worked over. The sinking of a winze from the 2600 to the 2800 and 3000 levels is under way. Sixty tons are being shipped daily from the Tuolumne, which tonnage will be increased within 30 days, according to Manager Paul A. Gow, who returned Wednesday night from several weeks spent in the east in connection with the Tuolumne affairs. Development will be pushed vigorously at the three properties now controlled by the Tuolumne Co.

Helena.

The net earnings of the Scratch Gravel Gold Mining Co., of which W. E. Cullen of Spokane is president, were \$119,947 for the 11 months ended Aug. 31, according to the official report of the management. The output of the property was 2847 tons during the period, and the net smelter returns were \$42 a ton. The main working shaft has been sunk to the 500 level on the incline of the vein, where a station has been cut and drifts started both ways. The deposit is said to be about 7 ft. wide, carrying a high-grade pay streak 12 to 30 ins. in width. Drifts also are being run east on the 300 level and west on the 250 level, and recent reports state that the ore opened in these workings is running about \$65 a ton.

Operation of the Franklin mine on Scratch Gravel from Dec. 20, 1914, to Aug. 15, 1916, show the mine produced

\$342,516.72 of ore. Expenses of operation were \$125,738.02, leaving a net profit of \$216,778.70. A total of 195 carloads of ore were shipped returning an average net profit of \$1111 per car. The mine has been taken over by a company organized by the heirs, so the record of its operations will no longer be available.

Dillon.

Dr. A. C. Sandberg of Butte, president of the National Oil Co. that is drilling a well on Muddy creek in the southern end of the county, was in Dillon last week attending a meeting of the board of directors, and while here stated that his company would let a contract for drilling a well on their oil property adjoining the Beaverhead-Alberta Oil & Gas Co., 9 miles south of here, where active drilling operations are now going on. The doctor was very enthusiastic in speaking of that oil field and especially the large deposits of oil shale there, and predicted that before long development work of these deposits would be made as he interested eastern capital in the proposition.

Red Lodge.

A group of placer claims staked out by George Peeples at the northern end of the Chapman bench, just below the mouth of Pat O'Hara creek, shows sensational values. There is no doubt that the discovery made by Peeples is the feeder for the Clarks Fork placer gold. Heretofore, there has been no gold discovered as far south as Pat O'Hara creek and it was always the belief that the gold in the river had its origin several miles north of that point. Peeples made the discovery right at the point where an old and formerly much-used trail crosses the river at a small flat north of the Chapman bench. Many Red Lodge residents have crossed that same trail hundreds of times. The claims staked out cover the ground crossed by the trail. Peeples traced his find for a considerable distance back from the river and found the evidence that he had struck it rich more and more convincing. The gold is of a much coarser grade than has been taken from the river further north and there is every sign that it exists in abundance.

Virginia City.

The Shafter mine at Summit, according to Manager A. H. Jones, is showing up well under development, and will soon become a steady producer.

Anaconda.

The Gold Leaf Mining Co. has been incorporated by F. D. Lutz, H. J. Hayes and P. E. White. The properties to be worked are situated in Granite and Ravalli counties, in what is known as the Frog Pond basin. The capital stock is \$200,000, with a par value of \$1 a share. The properties have been developed by a tunnel 1000 ft. in depth and other workings and those acquainted with it hold it as one of the most promising showings in the district.

NEVADA.

Goldfield.

Additional equipment for the Goldfield Con. flotation plant is scheduled to arrive within a short time, and the management expects to resume with the process within 40 days. An electric haulage system has been installed on the lower levels, preliminary to a heavy extraction of ore from the deep workings. Extensive developments are proceeding northerly from the Red Top-Laguna levels with good results. The mill at present is treating around 800 tons of ore daily, using the cyanide process. As soon as the flotation plant is operating at full capacity the material from the old dumps will be run through the cyanide department.

The Jumbo Extension Co. has taken a working option on the Kanrohat mine in Jefferson canyon, 6 miles northeast of Round Mountain. The property contains wide veins of mill ore and is equipped with a 50-ton mill, which has never been operated. The 564-ft. main tunnel will be driven 150 ft. further in hopes of intersecting the main vein system.

A large vein has been intersected at a depth of 900 ft. in the shaft of the Silver Pick. High-grade assays in gold and copper are being obtained. Sinking will be continued another 60 ft. to intersect another vein disclosed by the drill, and lat-

eral work started on the three distinct ledges. Late work proves there is a distinct ore channel west of the Columbia Mountain fault, with the veins dipping westerly, and many engineers believe the hitherto neglected west end of the district will soon support several producing mines.

The Diamondfield Black Butte Co. has installed a core drill and is preparing to prospect its holdings to a depth of 1000 to 2000 ft. Good ore has been opened on the 110 and 135 levels and these veins will be prospected thoroughly at depth. The company has arranged for steady shipments from its Orizaba mine, 30 miles north of Millers.

Luning.

Ore running 8 to 20% copper has been struck in the Anderson claim of the Nevada Champion group by lessees. The discovery was made at an approximate depth of 50 ft. below the glory hole level. In the Nevada Champion mine an ore body 10 to 50 ft. wide is being developed near surface. It is stated to range from 8 to 20% copper. Shipments are going out, but a car shortage is curtailing production.

Shipments have begun from the Luning-Idaho group, in the northern end of the district. A large tonnage of good-grade material is exposed. New York capital has become interested. Main offices have been moved from Luning to Reno. R. B. Todd is president.

Round Mountain.

While the season's supply of water available for treating placer ground in the Round Mountain Co.'s property has been exhausted for some time, the management, by adopting new methods, has prolonged the earning period to a considerable extent by adoption of methods commonly used in building operations. Since the water cannot be brought to the gold-bearing territory, the yardage is picked up with teams and sledges, carried over a bridge and dumped into the sluice boxes. This method of recovery, which is only partial for the ground covered, has shown the highest values for the year. It was commenced early in August, and the total for that month was 2150 yds., with a gross value of \$2.08 per yard. Another small cleanup, made Sept. 12th, yielded 871 yds. with a gross value of \$2.50 per yard. This process will be continued as long as practicable and will add several thousand dollars to the gross earnings for the season.

Manhattan.

An extra shift has been added by the Union Amalgamated, making it possible to do considerable additional development work which was not possible with only two shifts working. Developments for the past week have been very gratifying, as the ore faces have widened somewhat and the average values improved. The main ore shoot which had faulted at the 250 has been picked up by a raise from the 300 and shows good values as far as developed. The mine has been inspected by Directors James and William Forman, and President C. F. Wittenberg, who all expressed themselves as being highly pleased with the continued improvement in the mine. A number of improvements have been talked of which will include raising a 3-compartment vertical shaft after sinking the present incline another 100 ft. The ore in the bottom of the drift on the 500 level shows strong and clean with average values around \$80.

The south glory hole at the Big Pine has been opened into the new ore body beyond the fault. One machine is being kept at work in the south drift and raises will put up through this new ore body at 50-ft. intervals. Considerable difficulty has been experienced in getting a spiral test that would carry the desired tonnage into the mill, but this fault has been overcome and the tonnage will be increased to 400 tons daily.

Work on the Wall group continues the same as last week, with good values in ore production and mill values in the east drift on the hanging wall of the ledge, which is 20 ft. wide. Box samples for the first 2 days of the week ran \$83, due to striking a small rich shoot in the glory hole; 250 tons will be milled next week.

The Morning Glory property adjoins the White Caps, and is in line for similar ore bodies. L. K. Kountze and Zeb Kendall, both officers and heavy stockholders, visited the property last week and again this week. Kendall stated that it was the present intention to work the property at both ends, thus exploring the extension of the White Caps and

the Manhattan Con. ore bodies, both of which trend into the Morning Glory property.

NEW MEXICO.

Mogollon.

Cleanup at Fannie mine by Socorro Mining & Milling Co. for first half of September resulted in 16 bars gold and silver bullion and the usual tonnage of concentrates.

The new ore body recently opened on Clifton mine by the Oaks Co. continues to improve, and while the work is still confined to development, considerable ore is being shipped regularly to custom works.

Good progress in sinking for the week is reported from the Pacific, Johnson and Last Chance mines, the latter operated by Mogollon Mines Co. and the former two by Socorro Mining & Milling Co. More substantial development is now being done in the camp than at any time in the past.

A committee of Arizona farmers has just visited the mills, with the view of reporting progress on tailings disposal systems being installed, and it is understood they were well pleased and approved of the methods the companies are taking, at no little expense, to avoid running mill discharge into streams. The Socorro Co. is storing on their own premises while the Mogollon Mines Co. is building a 5-mile flume to convey the waste to a suitable site.

The annual consumption of sawed timber in this district is 500,000 board feet, and in addition about 40,000 feet of round timbers are used underground. The major portion of this has been furnished by one saw mill on Willow mountain, now operated by Kelly & Hunter. A plant on Mineral creek was more recently completed, with a board flume some 7 miles in length to convey the lumber to divide just above Mogollon, whence the company has an easy decent for most of its deliveries. The water after leaving flume will be piped to base of mountain and it is expected to thus develop 250 hp., sale of which has already been contracted. It is hoped to have the power plant in commission this following spring.

Two other available power sites are also being considered, either one of which is susceptible to development on a scale sufficiently large to meet the growing consumption. Cheaper power has long been recognized as the prime factor in arriving at a solution of lower cost figures in operation and the long-proven stability of the mines warrants a strong appeal to necessary capital for the installation.

OREGON.

Prairie City.

The chrome iron mines on Canyon mountain are now ready to ship. It is estimated that during the fall about 125 horses will be used in hauling the ore to this city over a road which has recently been completed to the mine. The bodies of this kind of ore occur in the district on surface and go to only very shallow depths. The body from which shipments are now to be taken is estimated to contain 60,000 tons.

Ashland.

Manager Bartlett of the Ashland mine reports that he has enough ore blocked to last the mill for 2 years. Some of the crushing and other milling machinery from the Baden mine on Gold Hill is being brought to the Ashland.

The Grey Eagle mine near Happy Camp, on the Klamath river road, Siskiyou county, has been purchased by W. B. Thompson, New York. The property contains about 500,000 tons of developed chalcopyrite ore, averaging 5%. For years the property has been developed by Dakin & Parish, San Francisco, and several outside holdings have been added to the original location. It is stated that the new owner will immediately start extensive developments and that a large reduction plant probably will be erected in 1917.

The Marin Andrew placer mine near Scott Bar, has been sold to R. J. Barber and associates, Boston. They are preparing to operate along broadened lines. The property ad-

joins the Milne mine and has been producing for 60 years. Numerous companies in the Happy Camp, Forks of Salmon, Sawyer Bar, Scott Bar and other placer districts are preparing for a brisk season with the first fall rains.

SOUTH DAKOTA.

Rochford.

A new working shaft is being sunk on the property of the Gold King Co. The shaft originally sunk to prospect the formation at the north end of the ground was an incline and not suitable for contemplated operations. The new shaft, which is 2-compartment, timbered with square sets, is located 100 ft. northeast of the incline and it is east of the ledge, which has an easterly dip of 13 degrees. The shaft is being sunk with the aid of a horse whim and is now down 40 ft., work having been under way for 5 weeks. The incline shaft, which was sunk 90 ft., disclosed a vein 60 ft. wide. The vein has been traced by its surface croppings and by shallow workings through practically the entire length of the property. The present intention is to sink several hundred feet and open the ledge at various levels, thus affording ore sufficient to operate a reduction plant. Previous announcements of the management state that English capital will be coming for the complete equipment of mine and proposed mill, as soon as the war is over. In the meantime, sufficient funds are being raised to keep development work in progress.

Deadwood.

The annual report of the Deadwood-Heidelberg Co. was recently made public and in part is as follows: Operations in the third year of development work done by the company on the property began July 16, 1915, after a shut-down of 5 weeks. The total expenditures on the property in 13½ months of continuous work aggregate \$4056.93, which funds were raised by the sale of stock. As the ore in the main drift began to sink below the level of the tunnel and therefore could not be reached, it was decided to crosscut both to the east and west with the intention of cutting new verticals underground. The east crosscut was continued for 55 ft. and the west crosscut for 325 ft. from the main drift. In the west crosscut several veins carrying low values in gold were tapped until a strong vertical was encountered running in a northeasterly direction and carrying good values in gold. Assay returns on the vertical ore in this new find show between \$15 and \$56 and the flat deposit showing a width of 7 ft. and over 15 ft. in thickness assays between \$4.20 and \$26.00. Average samples taken from top to bottom including the low grade shale gave over \$5 in gold. This is the most important find made during the year and of value principally due to the high grade of the vertical and the distance from the mouth of the tunnel giving good reasons to believe that the ore body is continuous and can be located on or close to the surface at a distance of about 300 ft. from the point of intersection underground. Five hundred ft. of trench work done on the surface during the months of August, September and October, 1915, disclosed, besides smaller veins carrying some low values in gold, a vertical 215 ft. northwest of the main Heidelberg vein and containing a good grade of ore. The highest assay on this No. 3 vein showed returns of \$28 in gold and an average of about \$4. An incline tunnel was driven on this vein for about 97 ft. The total amount of work done at a cost of \$4,056.92 during the last 13 months shows 500 ft. of surface trench work and 460 ft. of underground development. The property has now been opened up to a point where it has been possible to interest capital to spend a larger amount of money in sinking a shaft to quartzite and incidentally developing the upper shales.

UTAH.

Alta.

The water ditch has been completed, ventilating pipes are now being placed and the tracks straightened in the tunnel of the Alta Tunnel & Transportation Co. Plans are also being considered for the starting of work on the 200-ft. vein of

brecciated limestone that has been cut in the tunnel at a depth of 1200 ft. The management has not as yet decided at which point this work will be started but there are three promising points in the tunnel from which to start work. The vein, consisting of fragments of blue limestone, white soluble limestone and porphyry, all of which shows lead, copper and silver values scattered through, strikes east, crossing the direction of the tunnel which is being driven due south. At 100 ft. north from the brecciated vein is a northeast fissure carrying considerable manganese and iron. It will intersect the brecciated vein at 500 ft. west of the tunnel proper. The contact between the blue limestone and the brecciated vein also offers a promising point at which to start the work. There is in addition a water course that is considered promising for prospecting purposes.

Beyond the present breast, which is in 2045 ft. the management expects to cut the Flora Hagen vein with any round of shots.

The tunnel of the Hellgate Co. is now in 50 ft. The portal of the tunnel is near the creek bed of Little Cottonwood, south of and about 200 ft. vertically below the portal of the old Frederic tunnel. The new Wasatch mines drainage tunnel has been started about half a mile west of the Hellgate tunnel and will pass under the Hellgate ground and drain it to a depth of about 300 ft. Before deciding on the site for the new tunnel portal, the management did some prospecting work on a prominent vein which outcrops near the creek bed near the present portal. A vein was uncovered there for some distance. The ore in one place was 4 to 5 ft. wide, while the vein was uncovered for 75 ft. along the strike. The principal values are silver, copper, lead and gold. The Cardiff fault plane crosses the Hellgate property the full length of the group. The same limestone-quartzite contact that is found in the Cardiff makes through the Hellgate ground.

Beaver.

In reviewing operations the Antelope Star Manager Nebeker says that the main tunnel workings of the Star properties had been driven into the mountain 225 ft. and for 135 ft. the workings were in ore. It's a sulphide lead ore and there are some large blocks of high grade that give assay returns of 60% lead. In addition to this there is a portion of the deposit in the brecciated lime contact of a good mill grade that gives assay returns of 5 to 7% lead. While the property is not opened up extensively the management is of the opinion that the showing to date justifies the belief that enough of the milling ore will be developed to warrant the erection of a plant for treatment at the mine. By following the ore to the face of the present tunnel the company has proven up this deposit with 200 ft. of backs. The deposit has also been proven by a shaft which attained a depth of 65 ft., being sunk on the dip of the vein. One of the new pieces of work to be performed is the sinking of a winze from the tunnel level in ore. The tunnel is to be driven ahead at the same time this work is being done, as the tunnel is following the bedding into the higher part of the mountain. This work has been decided upon as a result of new financing that has been arranged, and the management expects to get out some of the high grade ore and make a shipment to the valley smelters soon.

The Hickory mine of the Majestic Mines Co. has been producing a little of late. The ground shows some immense channels, but most of the ore is too low grade to make it profitable to ship. Some of the ore bodies prospected have shown widths of 100 ft. A little more depth will probably prove that these extensive ore bodies have been leached out and the ore deposited at lower depths, where shipping values are anticipated. It is expected that 200 ft. more depth will get into the higher values. The work of sinking the main working shaft of the Hoosier Boy is going on with satisfactory progress in this respect. The 700 level has been passed and the miners are now making for the 800. Here a station will be cut and considerable prospecting work taken up.

Eureka.

All the new machinery at Tintic Standard has been installed with the exception of a blower fan which will be in soon. The new compressor which has been installed furnishes 3 drills and the three auxiliary hoists. One of these hoists

has been installed at the new shaft, another at the No. 2 winze, which has been sunk from the 1000 to the 1200 level, and the third is installed at the No. 3 winze, sunk from the 1200 level to the 1600. The new shaft has attained a depth of 100 ft. and a contract will be let to sink this shaft to the 1100 level. Bids for this work are now being received by the officials. It is planned to drive the shaft down with speed, as its completion will reduce the expense of handling ore already developed on the lower levels. It will also aid the ventilation problem for all time and thus reduce the operating costs. As the work of developing the ore body opened on the 1600 level progresses the ore body continues to grow. It has now been drifted on to the northwest for 35 ft., to the southwest for 40 ft. and to the south for 60 ft., with no walls in sight. The ore also occurs in the No. 1 winze 600 ft. south of the present workings on the 1600 level and 400 ft. above those workings.

A new copper shoot has been encountered in the north end of Iron Blossom's, Tintic mine. This was given out by J. W. Knight, who says further that the drift that is coming up on the 1700 level from the south is showing some copper stains. It is now about 2 months off from reaching its objective. The copper ore shoot as developed on the 1200 has shown such strong inclinations to go to further depth that a new winze has been started from that level to prove the ore to lower levels. On the 1200 level the shoot has been opened up 30 ft. The size of the ore body is even larger than where it has been developed on the 1100 level, but the values have been not quite so high. The vein on the 1200 is very strong and appears to be making to greater depths. Accordingly it has been determined by the management to sink the new winze just started at least 100 ft. deeper, or to the 1300 level. On the deepest workings in the Iron Blossom, the 1700 level, for some time a drift has been making rapidly to the north end of the property. The objective is to tap the new copper shoot. This drift has encountered some ore at intervals. The last report is that the face is now showing some encouraging stains. The face is now about 500 ft. from the shoot. Iron Blossom is now producing at the rate of 1000 to 1200 tons a week. The production in August was 64 carloads, or 3200 tons. So far in September the output has been 78 cars, estimated at 3750 tons.

WASHINGTON.

Spokane.

It is anticipated that the Intermountain Mining Co., which, on Oct. 20, will pay its initial ½-ct. dividend, or \$8250, will be able to maintain production steadily during the coming winter, arrangements having been made to secure electric power from a nearby plant during the cold period, and it is predicted that the dividend will be increased to 1 ct. in November, according to A. T. McDevitt, closely associated with the management, who returned recently from a visit to the property. "By adding a Harding pebble mill, the company's concentrator, originally a 100-ton daily capacity plant, now is able to treat from 140 to 150 tons a day," said Mr. McDevitt. "There are 33 men, working in three shifts, employed in the mine and mill, and ore bodies on the 200, 400 and 700 levels, averaging from 2 to 6 ft. wide, together with other shoots that have been opened in other parts of the property, assure reserves sufficient to keep the production up to the present rate for the next 5 years, even if no new supplies are opened. The company is shipping each month 300 tons of concentrates and crude ore. The crude ore runs 20% copper and carries 1½ ozs. silver. Shipments are being made to the B. C. Copper Co.'s smelter at Greenwood, under a 1-year contract. The freight charges are \$4.50 to \$6.50 a ton, determined by the value of the product shipped. The company's railroad has been gone over thoroughly, 1000 new ties put in and the entire line put in good condition. Timber needed during the winter in the mine has all been cut and is seasoning, and the only new equipment that may be needed is a Shay engine. All the company's bunkers on the main line are filled with ore waiting for cars and at the mine 2 carloads are ready. Shipments will increase from now on. President

Oscar Nordquist told me he could see no reason why this company should not pay 1 ct. a month in November and thereafter."

Chesaw.

After driving through 40 ft. of copper ore of good grade on the Cariboo, and not yet through the body, the British Columbia Copper Co. has increased its ore hauling force, and put on a third shift in the mine. The property lies about 4 miles northeast of Chesaw on Copper mountain, and is one of the group of four bonded in July to the company. The ore is being handled at the company's own smelter at Greenwood, B. C.

WISCONSIN-ILLINOIS.

Highland.

The New Jersey Zinc Co. has increased its mining activities in this district appreciably and shipping of carbonate zinc ore average better than a car daily. Much ore is held by small local concerns, who seem to be unable to obtain a market for their product.

Miffin.

Eagle-Picher Lead Co. through its local buyer has been invading this district, taking a car each from the Peni and B. M. & B. mines. Negotiations are pending for the sale of about 400 tons of high-grade blende held by the Peni Mining Co. Shipments for the district last week totaled 14 cars, 561 tons. The Big Tom mine, recently equipped, is now on a producing basis. A new 200-ton mill is nearing completion on the Yewdall lease for the Vinegar Hill Mining Co.

Platteville.

Reports from the field in general, for week ending Sept. 30, show shipments of 140 cars of zinc ore, all grades, to both separating plants and smelters, 5622 tons; only 1 car of lead ore cleared, 42 tons. Shipments of pyrites came from the Linden Zinc Co., 40 tons; Benton Roasters Co., 264 tons; Mineral Point Zinc Co., to prime western smelters, 424 tons; National Separators to General Chemical Co., 201 tons. The reserve of zinc ore at all points in the field is estimated at latest reports at 8000 tons; lead ore, 1000 tons; pyrites, 15,000 tons. The gross recovery wet concentrates for the week showed a falling off, only 4491 tons being reported. Net deliveries refined ore from separating plants to smelters, 3178 tons.

Prices for zinc ore showed improvement, top and 60% ore holding at \$58 base, with the range down to \$50 on seconds and medium grade. The basis of zinc content was raised, these figures applying on ores not under 54% zinc content. This made it more difficult for independent low-grade producers, and very little ore was marketed from this source.

Shipments from locals were light last week, East End, West Hill and Block-House Mining shipping 1 car each, 137 tons, and Hodge mine to Cuba, 2 cars, 87 tons. Unless low-grade zinc ore producers are soon enabled to unload some of their reserve ore many will be compelled to suspend operations.

Benton.

The Domestic Mining Co., a local organization, is meeting with big results in shaft sinking on the McCabe lease, which has been thoroughly explored with drills. Big ore deposits have been gone through in the main hoisting shaft. Jos. Piquett has the contract for sinking of a new shaft on the Meloy lease for the Vinegar Hill Zinc Co. The contract for the construction of the power and milling plant was awarded to Edward Sargent. Shipments of zinc ore for week of Sept. 30 were reported by Frontier Mining Co., 16 cars, 687 tons; New Jersey Zinc Co., 10 cars, 323 tons; Vinegar Hill Zinc Co., to separators, 12 cars, 515 tons; Fields Mining & Milling Co., under a new long term contract to Grasselli Chemical Co., 5 cars, 202 tons; to Galena Refining Co., 2 cars, 96 tons; Eagle-Picher Lead Co. took 9 cars of Wisconsin Zinc Co.'s high-grade refinery product; 4 cars were also sent to American Zinc Co., Hillsboro, 182 tons; Indian Mound Co. to Mineral Point, 2 cars, 83 tons; total, 60

cars, 2544 tons. Benton Roasters delivered 6 cars of fine pyrites from separating plant, 264 tons, to Grasselli Chemical Co.

Cuba.

Much excitement prevails in this district among operators following phenomenal strikes of zinc ore by the Standard Metals Co. of Chicago. The new find is made on the old Dall Mining Co.'s leasehold and on the Coulthard lands adjoining. The range makes at a uniform depth of 140 ft. and has been drilled out for three-quarters of a mile in length. The work of proving fell to the lot of John Anthony, a local mining man, who is interested.

A big revival in zinc mining is noted in this camp following a dormant period of over 2 years. National Separating Works shipped 5 cars high-grade zinc ore to Illinois Zinc Co., 196 tons, and to Granby Con., 44 tons; Linden Zinc Co., now operating the Campbell Separating Works, made delivery of first car high-grade ore to DePue, 40 tons; Utt-Thorne Co. delivered a car to roasters at Benton, 40 tons; Carr Mining Co., a new organization, made initial shipment to Sandoval Zinc Co., 31 tons, and Eagle-Picher Lead Co., another car high-grade from the Linden Zinc Co., 40 tons. Receipts of raw ore during the week totaled 19 cars, 814 tons.

Hazel Green.

The Big Three, the usual weekly shippers, the Kennedy, Cleveland and Lawrence mines, responded last week with 11 cars all told, 480 tons. McMillan Mining Co. is installing new and heavier pumping machinery. A new producer is being developed by the Rio Mining Co. Monmouth Zinc Co. is again producing.

New Diggings.

The Vinegar Hill Zinc Co. has installed a cage and cars at the Blackstone mine. These replace old hoisting outfits and cans. The C. A. T. mine of the Wisconsin Zinc Co. is now operating steadily with a new rig and making a 45% zinc concentrates. The Longhorn mine, another new applicant, will be complete and fully equipped by Nov. 1. Both plants have a capacity for handling 300 tons of mill rock daily.

Shullsburg.

Rodhams Mining Co. continue shipments, a car high-grade blende going to Lanyon Zinc Co., 28 tons; Winskill mine shows big, and shipments were heavy, last week's report showing 7 cars out to Galena, 303 tons.

Galena.

Restricted shipments from regular producers show here last week, the Black-Jack mine being able to make only 3 cars, 112 tons; Federal mine, 3 cars, 120 tons; North Unity, 2 cars, 89 tons; Pencroft Mining Co., a new producer, made initial shipment of a car to Cuba, 40 tons. Separators going on up district ore sent 2 cars to Lanyon Zinc Co., 93 tons; Edgar Zinc Co., 2 cars, 82 tons, and Wisconsin Zinc Co. to LaSalle, 4 cars, 158 tons.

WYOMING.

Lander.

Although the ceded part of the Shoshone reservation has been opened up regulations regarding leasing have as yet not been drawn up. The leasing will be handled by reservation authorities and the Indian department officials will rule on priorities. As soon as the leases are granted there will be a lot of drilling done on the ceded part of the reservation as several companies are holding rigs now to put on the leased land when the title is cleared. When the president signed the act there was a rush from all over the country to file applications for the reservation lands which include the Pilot and Maverick Springs fields, and several other likely localities. Filings were made in both the general land office and the Indian office at Washington, and at the land office at Lander, and the Indian office at Fort Washakie. As many as 11 applications for the same land are on file in different places.

Basin.

Progress is being made in this district and the Liberty Oil & Gas Co., operating on the Howell place, northwest of

town, with a Star rig, is reported down over 200 ft., and the formation is conforming to their reports previous to drilling. W. L. Russell and associates, who have a Star on Greybull, are reported down 1000 ft. The Liberty Oil & Gas Co. has installed a new lighting plant at their rig on the Greybull. It is making good progress with its hole. Scott Mills, drilling on the Pease lease, is making good progress and expects to bring in a good well soon. The Great Western well on the Coffield place has been cleaned out and has flowed three times during the past week. They are still bothered some with sand coming in the well and expect to get the pump working. The company will commence another well as soon as this one is disposed of.

CANADA.

BRITISH COLUMBIA.

Salmo.

The lower tunnel on the Hudson Bay is in 1650 ft. and it is expected to reach the ledge outcropping on surface at 1750 ft. Stringers of zinc sulphide have already been encountered, denoting the proximity of the objective. The upper workings have proved an ore body 1200 ft. long and from 15 to 75 ft. wide. The ledge for that distance is filled with zinc carbonate ore having 15%. In this body there occurs a streak from 4 to 8 ft. wide, which assays 38% zinc and from this all shipments have come. The upper workings are confined to two levels. The main tunnel level is 200 ft. below the outcrop. The winze level is 100 ft. deeper. The new tunnel will cut the ledge nearly under the winze at an added depth of 575 ft. During the period that the mine has been under development by its present owners shipments of ore have been maintained at an average rate of 50 tons daily. Nearly all the ore was taken out in the course of development and without resort to stoping further than to demonstrate the extent of the high-grade shoots. The Hudson Bay has for some time been a Hayden-Stone enterprise. J. L. Bruce is general manager and W. S. Grether is resident manager. Spokane people still are among its largest shareholders. Maurice W. Bacon is president and William E. Cullen is treasurer. Though not a director, R. K. Neill is in general charge of the company's property at present.

Hedley.

Development has indicated that the general average value of the ore will be \$10 to \$11 the ton, according to a recent report from President I. L. Merrill of the Hedley Gold Mining Co. The increasing baseness of the product with depth, which increases the concentrate tonnage and reduces the grade, has necessitated a change in the treatment system, and a straight cyanidation system is being installed. The ore reserve is estimated at 423,522 tons, averaging \$10.39 per ton. Of this, 35,025 tons, rated at \$8.52 per ton, are in the old workings above No. 4 tunnel, and below that are 388,527 tons, averaging \$10.55 per ton, including 75,000 tons of \$11 ore below the 800 level. The output of the property in 1915 was 74,265 tons, all of which was milled, and the total recovery was \$796,592. Operating expenses were \$421,846, including \$38,938 expended perfecting the new hydro-electric plant and in betterments to other equipment and the camp buildings. The hydro-electric station, commissioned Jan. 2, 1915, at a cost of \$192,000, or \$8000 less than the estimated price, is on the Similkameen river, just below the mouth of Twenty-Mile creek, and furnishes power to operate the 40-stamp mill and the mine machinery, as well as current to illuminate the camp and the underground.

Sandon.

Conditions in the Slocan region are better than in any previous period of its history, and the district offers unusually attractive inducements for investment.

The Slocan Star Co. has been greatly hindered in its operations by lack of sufficient power, for which reason both mine and mill are working only one shift each. All the machinery for the new hydro-electric power plant, with the exception of the wheel and one length of pipe, has arrived and is being installed, so that the plant may be put into operation within a few days. During August the company

shipped 5 cars of silver-lead ore and concentrates, which netted \$16,000 over and above operating expenses of \$10,000. The zinc shipments, whose proceeds are not included in the above figures, totaled 110 tons.

Greenwood.

At Copper Mountain the British Columbia Copper Co. is installing a pumping plant to elevate water from the Similkameen river to a distributing point 1700 ft. above the river through a pipe line 6000 ft. long. The pumping equipment will consist of triplex pumps and the pipe line will be composed of 4-in. high pressure hydraulic pipe in the lower section and 6-in. steel pipe at the discharge. The water will be used to supply the mine, the camp and a 50-ton experimental mill. The mill will be devoted to the working out of a concentration process preliminary to the erection of a 2000-ton plant on the Similkameen.

Three Forks.

The Rambler-Cariboo has much larger reserves of ore than it is usually credited with. Mining operations are proceeding on the 8, 9, 10, 12 and 13 levels, from which 75 tons of ore are being sent daily to the mill. Shipments of lead ore and concentrates average around 175 tons a month and the mill also produces about 75 tons of 33% zinc concentrates monthly. Of the latter product there is now about 1000 tons on hand awaiting retreatment in the Kaslo custom concentrator, where it will be worked up to a satisfactory shipping product. One stope above the No. 9 level shows 16 to 18 ft. of first-class concentrating ore with a streak of clean galena from 1 to 2 ft. wide in the face.

The Lucky Jim mine has developed a large tonnage of ore and by the recent completion of an upraise from a crosscut from the No. 5 tunnel to the big stope is now in shape to produce economically. It is shipping high-grade mill feed only to the Rosebery concentrator and mine run ore to Kaslo. The latter averages 21% zinc, 1.3% lead and 16% iron. The preliminary runs of the magnetic separator at the Kaslo mill yielded a product assaying 46% zinc and between 8 and 9% iron.

New Denver.

One of the finest ore showings is that in the Sovereign mine, recently bonded by Clarence Cunningham, who is operating the Queen Bess and Wonderful as well and is about to take over the Idaho-Alamo, all four properties being now on a producing basis. The intermediate level on the Sovereign shows between 3 and 4 ft. of clean galena in the face, and has proved the shoot for a length of 30 ft. already. At one point the clean ore is fully 5 ft. wide. There are 70 tons of ore sacked and ready to ship to the smelter.

In the Queen Bess, Cunningham is mining an entirely new ore shoot on the Nos. 5 and 6 levels. Owing to its being in virgin ground it has a good chance of going to the surface, and being found also at depth in the No. 9 level. It averages between 2 and 3 ft. of clean galena. He is shipping regularly also from the Wonderful.

ONTARIO.

Cobalt.

Recent reports show a good production from Kerr Lake during August with an output of 246,488 ozs. of silver, comparing with 184,697 ozs. in January, 163,995 in February, 214,902 in March, 225,423 in April, 234,598 in May, 237,942 in June, and 211,000 in July. March was the first month since 1910-11 that the company succeeded in passing the 200,000 mark. Now it is producing 250,000 ozs. per month. It probably surpasses the 250,000 ozs. per month mark since the above figures are exclusive of the Caribou-Cobalt production, in which company Kerr Lake holds the controlling interest. Eight months' production from Kerr Lake, proper, was 1,719,045 ozs.

Dome Lake, which has been closed 3 weeks, is now busy on the extension of its new mill. A new Hardinge ball mill is being installed, which will increase the capacity from 50 to 150 tons per day, giving an average output of 5600 tons per month. The mill extension will be in operation this fall.

Port Arthur.

The option on the St. Anthony gold mine held by the Dominion Reduction and Kerr Lake companies has been taken

up. It is located near Sturgeon lake, in the Rainy River district and has been under option for a year, during which time \$90,000 was spent. Two-thirds of the St. Anthony is owned by the Dominion Reduction and one-third by Kerr Lake. The total amount paid for the property has not been made public but a payment of \$60,000 was made recently. The St. Anthony was opened 10 years ago, but owing to financial difficulties it was closed down a few years ago. Considerable gold has been mined from the property. Owing to nature of ore some difficulties were encountered in the treatment of it.

Schumacher.

A new shaft known as No. 4 has been started at the Schumacher mine and is now down 30 ft. It is situated on the opposite side of the town and on this account it will probably be necessary to construct an aerial tramway as a means of transporting ore across the street to the mill. A new machine shop has been built and equipped on the property in which the company can now do their own repair work.

MEXICO.

Monterey.

According to advices that have been received from the El Oro mining district, all three of the larger mining companies operating there are now working under almost normal conditions. It is stated by Dr. H. A. Geitz, surgeon for the El Oro Mining & Railway Co., at El Oro, who passed through here a few days ago on his way east for a brief business visit, that the decree which General Carranza recently issued that all mines in the republic must be placed in operation within 60 days or the properties would be taken over by the government, is causing a general renewal of mining activities in all of the districts of Mexico, with the possible exception of those that are situated in localities where revolutionary and brigand bands are still operating. It was stated by Dr. Geitz that there has been no destruction of foreign-owned property at El Oro. Most of the mines in that camp are owned by Britishers. La Esperanza mine at El Oro, which at one time produced at the rate of \$1,000,000 gold per month, is now being worked on a big scale by improved machinery. Mine laborers at El Oro are paid at the rate of 31 pesos Carranza currency per week, which is equivalent to about 95 cts., basing the currency of the de facto government as worth 3 cts. There is plenty of corn on hand for the people of El Oro, Dr. Geitz said. The camp has been sacked by revolutionists three times. It is now in control of the Carranzistas.

NICARAGUA.

Tunkey.

The Eden Mining Co., controlled by the Tonopah Mining Co.'s stockholders, has made large expenditures in Pis Pis mining district, near Tunkey, on Ban-ban river. A cyanide-leaching plant of 100 tons daily capacity is under construction, a hydro-electric power plant has been built, and a railroad 13 miles in length has been completed from Tunkey to the company's mine, in which there are large bodies of low-grade gold ores, amenable to cyanide treatment. The locality is reached by launch, 70 miles up stream on Prinsapolka river, thence a shorter distance up the Ban-ban to Tunkey. Conditions in Nicaragua, with respect to laws, regulations and protection, are considered satisfactory.

Bluefields.

W. B. Milliken and H. E. Fredericks, Denver, Colo., owners of Linda Ventura mine, situated near Wa Wa river, on the Atlantic coast, have built a wet-crushing, sliming and sand-leaching cyanide plant of 2000 tons per month capacity, and have constructed a narrow-gauge railroad from the river to the plant and mine. The mine is producing and the mill has begun operating. The mine has a vein of gold ore 17 ft. wide, running \$7 to \$8 per ton. One shoot of ore runs much higher. Plans are made for putting in a hydro-electric power plant on the property. Their port of entry is Bluefields, from which place the route is by launch up Wa Wa river.

World's Index of Current Literature

A Weekly Classified Index to Current Periodical and other Literature, Appearing the World Over Relative to Mining, Mining Engineering, Metallurgy and Related Industries, in Four Parts.

Part 1. *Geology*—(a) Geology; (b) Ore Genesis; (c) Mineralogy.

Part 2. *Ores and Metals*—(a) Metals and Metal Ores; (b) Non-Metals.

Part 3. *Technology*—(a) Mines and Mining; (b) Mill and Milling; (c) Chemistry and Assaying; (d) Metallurgy; (e) Power and Machinery.

Part 4. *General Miscellany* (including Testing, Metallurgy, Waste, Law, Legislation, Taxation, Conservation, Government Ownership, History, Mining Schools and Societies, Financial, etc.

Articles mentioned will be supplied to subscribers of Mining and Engineering World and others at the prices quoted. Two-cent stamps will be received for amounts under

\$1. Subscribers will be allowed a discount of 5 cts. if the price of the article exceeds 50 cts. The entries show:

(1) The author of the article.

(2) A dash if the name is not apparent.

(3) The title, in italics, of the article or book. Titles in foreign languages are ordinarily followed by a translation or explanation in English.

(4) When the original title is insufficient a brief amplification is added. This addition is in brackets.

(5) The journal in which the article appeared; also the date of issue, and the page on which the article begins.

(6) Number of pages. Illustrated articles are indicated by an asterisk (*).

Saint-Smith, Cecil E.—*Robson's Lodes of Wolfram, Tin, Etc., Tinaroo, North Queensland*. [An account of exploring operations and the geology and occurrence of the minerals].—Queen. Govt. Mg. Jnl. Aug. 15 1916; p 368; pp 1½*; 35c.

Ore, Genesis

Loftus, N.—*New Theory for Coal Formation*. [Says that coal was formed from the decomposition of carbon dioxide, which gas was near the earth's surface before mountains were made].—Coal Tr. Bull. Sept. 15 1916; p 41; pp 1½; 25c.

Robinson, Heath M.—*The Ozokerite Field in Central Utah*. [Abst. from a U. S. G. S. bulletin. Genesis, properties, production, concentration, etc., are considered].—Mg. World Sept. 16 1916; p 497; pp 1¾*; 10c.

Mineralogy and Petrography

Schroeder, J.—*The Solubility of Leucite in Sulphurous Acid*. [Details of the chemistry and methods applied thereto].—Jnl. Ind. & Engg. Chem. Sept. 1916; p 779; pp 1; 60c.

Young, George J.—*The Selection of a Method for Ore Treatment*. [On meth-

ods of testing and investigating new ores for refining treatment].—Met. & Chem. Engg. Sept. 15 1916; p 297; pp 2¾; 35c.

II. ORES AND METALS

(I) METALS AND ORES

Copper

De Wolf, William P.—*Yavapai County, Arizona, Mines and Mills*. [A general review of current conditions, with some detailed information].—Mg. World Sept. 16 1916; p 503; pp 1¾; 10c.

Maguire, Don.—*The Copper Mines of Wolf Mountain, Cache County, Utah*. [A general and geological description of the district].—S. L. Mg. Rev. Sept. 15 1916; p 17; pp 2½*; 25c.

Matley, H. A.—*Canadian Metal Trades and Preparedness*. [Deals with the production and market prices of lead and copper in Canada. Separate reviews of provinces are given].—Canadian Mg. Inst. Bull. Sept. 1916; p 783; pp 7; 50c.

Scott, W. A.—*Mining Operations in Bingham Camp, Utah*. [Describes operations of the more important properties].—Mg. World Sept. 16 1916; p 491; pp 1¾; 10c.

—*British Columbia Annual Report of the Minister of Mines for 1915*. [Reviews metal production in general for the province and in detail for operating companies].—Mg. Engg. & Elect. Rec. Aug. 1916; p 76; pp 3½; 35c.

—*New South Wales in 1915*. [Reviews the production of metals in the country].—Mg. Jnl. Sept. 2 1916; p 596; pp 2; 35c.

—*Quebec Mining Industry—A Review for the First Half of 1916*. [Brief accounts of operations at various properties].—Canadian Mg. Inst. Bull. Sept. 1916; p 796; pp 4; 50c.

Gold Fields and Mining

Capps, Stephen R.—*Mining in the Willow Creek District, Alaska*. [Abst. from a U. S. G. S. bulletin. Reviews the operations of the more important properties in the district].—Mg. World Sept. 16 1916; p 499; pp 2; 10c.

De Wolf, William P.—*Yavapai County,*

Arizona, Mines and Mills. [A general review of current conditions, with some detailed information].—Mg. World Sept. 16 1916; p 503; pp 1¾; 10c.

Tucker, W. B.—*Mines and Mineral Resources of Amador, Calaveras, Tuolumne*. [Economic mineral products are reviewed by separate descriptions of deposits and mines, with some information on the condition of the country].—Calif. Mg. Bur.; pp 180*.

—*New South Wales in 1915*. [Reviews the production of metals in the country].—Mg. Jnl. Sept. 2 1916; p 596; pp 2; 35c.

Gold Milling, Metallurgy, Etc.

See Mill and Milling, Metallurgy, Chemistry, Assaying, Etc.

Iron Ores and Mining

Johnson, J. E., Jr.—*Blast Furnace Products*. [Speaks of the pig products used later for steel-making, foundry iron, puddling iron and ferro alloys].—Met. & Chem. Engg. Sept. 15 1916; p 324; pp 4¼; 35c.

Reifsneider, L. B.—*Underground Mining in Cuba*. [A method which does not interfere with operations above in surface mining. The stopes are filled after being worked out].—E. & M. J. Sept. 16 1916; p 509; pp 2¾*; 25c.

Rossmann, L. A.—*Nashwauk Iron-Washing Plants*. [Describes a small plant for washing and concentrating high-silica ores. Hydraulic principals are used in the machines].—E. & M. J. Sept. 16 1916; p 491; pp 2¾*; 25c.

Iron and Steel

Benedicks, Carl.—*A New Thermo-Electric Method of Studying Allotropic Changes in Iron or Other Metals*. [Abst. from a paper read before the British Iron & Steel Inst.].—Met. & Chem. Engg. Sept. 15 1916; p 337; pp 3; 35c.

Fechtchenkotchopovsky, S. A.—*Cementation of Iron*.—Rev. Soc. Russe de Metall, 1914; No. 1; p 245; pp 65.

Janssen, W. A.—*Use of Titanium in Steel Castings*. [A paper read before the American Foundrymen's Assn. telling of some of the advantages of ferro-titanium as a deoxidizer].—I. Tr. Rev. Sept. 14 1916; p 507; pp 5*; 25c.

Iron and Steel: Foundry and Furnace Practice

Johnson, J. E., Jr.—*Blast Furnace Products*. [Speaks of the pig products used later for steel-making, foundry iron, puddling iron and ferro alloys].—Met. & Chem. Engg. Sept. 15 1916; p 324; pp 4¼; 35c.

Osann, B.—*Behavior of Sulphur in the Blast Furnace*. [The reduction is regarded as taking place in the semi-solid magma].—Stahl & Eisen 1916; No. 36; p 210; pp 5; 35c.

Lead

De Wolf, William P.—*Yavapai County, Arizona, Mines and Mills*. [A general review of current conditions, with some detailed information].—Mg. World Sept. 16 1916; p 503; pp 1¼; 10c.

Matley, H. A.—*Canadian Metal Trades and Preparedness*. [Deals with the production and market prices of lead and copper in Canada. Separate reviews of provinces are given].—Canadian Mg. Inst. Bull. Sept. 1916; p 783; pp 7; 50c.

Speed, F. B., Jr.—*Lead-Zinc Mining in Virginia*. [A review of operations].—E. & M. J. Sept. 16 1916; p 511; pp ¾; 25c.

—*British Columbia Annual Report of the Minister of Mines for 1915*. [Reviews metal production in general for the province and in detail for operating companies].—Mg. Engg. & Elect. Rec. Aug. 1916; p 76; pp 3½; 35c.

Silver

De Wolf, William P.—*Yavapai County, Arizona, Mines and Mills*. [A general review of current conditions, with some detailed information].—Mg. World Sept. 16 1916; p 503; pp 1¼; 10c.

—*British Columbia Annual Report of the Minister of Mines for 1915*. [Reviews metal production in general for the province and in detail for operating companies].—Mg. Engg. & Elect. Rec. Aug. 1916; p 76; pp 3½; 35c.

Silver Milling, Metallurgy, Etc.

See Mill and Milling, Metallurgy, Chemistry, Assaying, Etc.

Tin

Saint-Smith, Cecil E.—*Malvern Tin Mine, Gurrumbah, North Queensland*. [A description of the property, its operation and mode of occurrence of the ores].—Queen. Govt. Mg. Jnl. Aug. 15 1916; p 367; pp 2*; 35c.

Saint-Smith, Cecil E.—*Robson's Lodes of Wolfram, Tin, Etc., Tinaroo, North Queensland*. [An account of exploring operations and the geology and occurrence of the minerals].—Queen. Govt. Mg. Jnl. Aug. 15 1916; p 368; pp 1½*; 35c.

—*New South Wales in 1915*. [Reviews the production of metals in the country].—Mg. Jnl. Sept. 2 1916; p 596; pp 2; 35c.

Tungsten

De Wolf, William P.—*Yavapai County, Arizona, Mines and Mills*. [A general review of current conditions, with some detailed information].—Mg. World Sept. 16 1916; p 503; pp 1¼; 10c.

Saint-Smith, Cecil E.—*Robson's Lodes of Wolfram, Tin, Etc., Tinaroo, North Queensland*. [An account of exploring operations and the geology and occurrence of the minerals].—Queen. Govt. Mg. Jnl. Aug. 15 1916; p 368; pp 1½*; 35c.

Zinc

De Wolf, William P.—*Yavapai County, Arizona, Mines and Mills*. [A general review of current conditions, with some detailed information].—Mg. World Sept. 16 1916; p 503; pp 1¼; 10c.

Parmelee, H. C.—*Recent Developments in Zinc Concentration Practice in the Joplin District, Missouri*. [Details of results on the jigging and table methods now used. The possibilities of flotation are also reviewed].—Met. & Chem. Engg. Sept. 15 1916; p 319; pp 2¾; 35c.

Speed, F. B., Jr.—*Lead-Zinc Mining in Virginia*. [A review of operations].—E. & M. J. Sept. 16 1916; p 511; pp ¾; 25c.

—*British Columbia Annual Report of the Minister of Mines for 1915*. [Reviews metal production in general for the province and in detail for operating companies].—Mg. Engg. & Elect. Rec. Aug. 1916; p 76; pp 3½; 35c.

—*New South Wales in 1915*. [Reviews the production of metals in the country].—Mg. Jnl. Sept. 2 1916; p 596; pp 2; 35c.

—*Quebec Mining Industry—A Review of the First Half of 1916*. [Brief accounts of operations at various properties].—Canadian Mg. Inst. Bull. Sept. 1916; p 796; pp 4; 50c.

(II) NON-METALS**(A) FUELS****Coal Fields and Mining**

Cameron, W. E.—*The Ipswich Coal Field, Queensland*.—Queen. Govt. Mg. Jnl. Aug. 15 1916; p 371; pp 1*; 35c.

Crankshaw, H. M.—*Mining Methods Employed in the Anthracite Field*. [A description of the stratigraphy and details of methods of underground operation and mining].—Coal Age Sept. 1916; p 452; pp 4*; 20c.

Gray, F. W.—*Nova Scotia Coal Production*.—Canadian Mg. Inst. Bull. Sept. 1916; p 891; pp 2; 50c.

Loftus, N.—*New Theory for Coal Formation*. [Says that coal was formed from the decomposition of carbon dioxide, which gas was near the earth's surface before mountains were made].—Coal Tr. Bull. Sept. 15 1916; p 41; pp 1½; 25c.

Pearce, William.—*Consumption of Coal in the Prairie Provinces*. [Details for provinces, prices, etc., are included. Considerable of the information is tabulated].—Canadian Mg. Inst. Bull. Sept. 1916; p 790; pp 5½; 50c.

Powell, J. W.—*The Season of Explosions*. [Treats on the danger of winter as a time when most mine explosions occur].—Coal Age Sept. 16 1916; p 458; pp 2¼; 20c.

Reed, Frank.—*Coal Mining Under the River Waikato and Lake Hakanoa, New Zealand*. [Abst. from the annual report of the government].—Colly Guard. Sept. 1 1916; p 399; pp 2½*; 35c.

Tompkins, Norton.—*Explosive Gas in Coal Mines*. [Information gained while studying evidence in regard to Bath thermal springs].—Coal Tr. Bull. Sept. 15 1916; p 48; pp 3; 25c.

—*British Columbia Annual Report of the Minister of Mines for 1915*. [Reviews metal production in general for the province and in detail for operating companies].—Mg. Engg. & Elect. Rec. Aug. 1916; p 76; pp 3½; 35c.

—*Coal Storage Plant on the Monongahela Innovation for River Operators that Is Arousing Keen Interest*. [A

description of the storage plant is given].—Coal Tr. Bull. Sept. 15 1916; p 35; pp 1½; 25c.

—*Iowa State Mine Inspectors' Report for the Biennial Period Ending Dec. 31, 1915*. [Reviews operations by counties, giving mine production and new equipment installed at mines, with accidents in the district in tabulated form].—State Mg. Bur. Report; pp 112.

—*Mechanical Equipment at Point-No-Point*. [Details of coal, water and steam handling at the Essex plant of the Public Service Electric Co., New Jersey].—Pract. Eng. Sept. 15 1916; p 771; pp 15¼*; 20c.

—*New South Wales in 1915*. [Reviews the production of metals in the country].—Mg. Jnl. Sept. 2 1916; p 596; pp 2; 35c.

Petroleum

Cox, Thomas.—*Methods and Costs of Producing Crude Petroleum in California*. [Details are given, with both tables, description and curves].—West. Engg. Sept. 1916; p 347; pp 6½*; 25c.

—*Chlorination Aided by Actinic Light*. [Speaks of chlorination with respect to hydro-carbons and other petroleum products].—Mg. World Sept. 16 1916; p 506; pp 1*; 10c.

—*Pipe-Line Transportation of Petroleum*. [Full financial, cost, construction and operation accounts of various pipe lines in U. S. are given].—U. S. Federal Trade Commission Report; pp 467*.

III. TECHNOLOGY**MINES AND MINING****Prospecting**

Brothers, Charles S.—*Mining and Prospecting in National Forests*. [Discusses the law affecting prospecting in national forests].—Mg. World Sept. 16 1916; p 493; pp 1¼; 10c.

Dunstan, B.—*Queensland Mineral Deposits, Australia*. [A detailed description of nature of occurrence, production, prospects and methods of concentration of asbestos ores].—Queen. Govt. Mg. Jnl. Aug. 15 1916; p 372; pp 3½*; 35c.

Shafts and Shaft Sinking

Reifsnider, L. B.—*Underground Mining in Cuba*. [A method which does not interfere with operations above in surface mining. The stopes are filled after being worked out].—E. & M. J. Sept. 16 1916; p 509; pp 2¾*; 25c.

Sayre, E. A.—*Comparison of Two Methods of Shaft Sinking Through Soft Material*. [Abst. of a paper read before the A. I. M. E.].—Engg. & Cont. Sept. 20 1916; p 259; pp 5¼*; 20c.

Tunnels and Tunneling

Tillson, B. F.—*Hammer Drill Records at the Franklin Mines, New Jersey*. [From a paper read before the A. I. M. E. Results obtained in drifting, stopping, raising, etc., are given, with costs].—Comp. Air Sept. 1916; p 8123; pp 2½; 20c.

Mine Gas

Tompkins, Norton.—*Explosive Gas in Coal Mines*. [Information gained while studying evidence in regard to Bath thermal springs].—Coal Tr. Bull. Sept. 15 1916; p 48; pp 3; 25c.

Ventilation

Crankshaw, H. M.—*Mining Methods Employed in the Anthracite Field*. [A description of the stratigraphy and details of methods of underground operation and mining].—Coal Age Sept. 1916; p 452; pp 4*; 20c.

Supports: Timbers, Props, Stowing

Crankshaw, H. M.—*Mining Methods Employed in the Anthracite Field*. [A description of the stratigraphy and details of methods of underground operation and mining].—Coal Age Sept. 1916; p 452; pp 4*; 20c.

Sayre, E. A.—*Comparison of Two Methods of Shaft Sinking Through Soft Material*. [Abst. of a paper read before the A. I. M. E.].—Engg. & Cont. Sept. 20 1916; p 259; pp 5¼*; 20c.

Hoists and Hoisting

— *Hoist Recorder for Mine and Elevators*.—Mg. World Sept. 16 1916; p 501; pp 1*; 10c.

— *Surface Plant at Brodsworth Main Colliery, England*. [Turbines using mixed pressure steam are used. Hoist, boilers, compressed air, etc., are described].—Colly Guard. Sept. 1 1916; p 401; pp 1½*; 35c.

Transport

— *Pipe-Line Transportation of Petroleum*. [Full financial, cost, construction and operation accounts of various pipe lines in U. S. are given].—U. S. Federal Trade Commission Report; pp 467*.

Haulage and Conveying

Crankshaw, H. M.—*Mining Methods Employed in the Anthracite Field*. [A description of the stratigraphy and details of methods of underground operation and mining].—Coal Age Sept. 1916; p 452; pp 4*; 20c.

Green, Ravul.—*Actual Costs of Mine Haulage by Horses and Compressed Air*. [Abst. from the Canadian Mg. Inst. Bulletin. In the comparison detailed costs are given].—Comp. Air Sept. 1916; p 8116; pp 2; 20c.

Scott, W. A.—*Mining Operations in Bingham Camp, Utah*. [Describes operations of the more important properties].—Mg. World Sept. 16 1916; p 491; pp 1¾; 10c.

Storage

— *Coal Storage Plant on the Monongahela Innovation for River Operators that Is Arousing Keen Interest*. [A description of the storage plant is given].—Coal Tr. Bull. Sept. 15 1916; p 35; pp 1½; 25c.

Accidents

Powell, J. W.—*The Season of Explosions*. [Treats on the danger of winter as a time when most mine explosions occur].—Coal Age Sept. 16 1916; p 458; pp 2¾; 20c.

— *"Air Blasts" in Mines* [Treats on these occurrences in foreign countries, principal among which is India].—Comp. Air Sept. 1916; p 8108; pp 2; 20c.

— *Iowa State Mine Inspectors' Report for the Biennial Period Ending Dec. 31, 1915*. [Reviews operations by counties, giving mine production and new equipment installed at mines, with accidents in the district in tabulated form].—State Mg. Bur. Report; pp 112.

Labor and Management

— *Iowa State Mine Inspectors' Report for the Biennial Period Ending*

Dec. 31, 1915. [Reviews operations by counties, giving mine production and new equipment installed at mines, with accidents in the district in tabulated form].—State Mg. Bur. Report; pp 112.

— *Welsh Miners' Wages, England*. [A general discussion of the same with wages given at various times].—I. & C. Tr. Rev. Sept. 1 1916; p 246; pp 1*; 35c.

Production

Dunstan, B.—*Queensland Mineral Deposits, Australia*. [A detailed description of nature of occurrence, production, prospects and methods of concentration of asbestos ores].—Queen. Govt. Mg. Jnl. Aug. 15 1916; p 372; pp 3½*; 35c.

Gray, F. W.—*Nova Scotia Coal Production*.—Canadian Mg. Inst. Bull. Sept. 1916; p 801; pp 2; 50c.

Matley, H. A.—*Canadian Metal Trades and Preparedness*. [Deals with the production and market prices of lead and copper in Canada. Separate reviews of provinces are given].—Canadian Mg. Inst. Bull. Sept. 1916; p 783; pp 7; 50c.

Pearce, William.—*Consumption of Coal in the Prairie Provinces*. [Details for provinces, prices, etc., are included. Considerable of the information is tabulated].—Canadian Mg. Inst. Bull. Sept. 1916; p 790; pp 5½; 50c.

Robinson, Heath M.—*The Ozokerite Field in Central Utah*. [Abst. from a U. S. G. S. Bulletin. Genesis, properties, production, concentration, etc., are considered].—Mg. World Sept. 16 1916; p 497; pp 1¾*; 10c.

— *British Columbia Annual Report of the Minister of Mines for 1915*. [Reviews metal production in general for the province and in detail for operating companies].—Mg. Engg. & Elect. Rec. Aug. 1916; p 76; pp 3½; 35c.

— *Iowa State Mine Inspector's Report for the Biennial Period Ending Dec. 31 1915*. [Reviews operations by counties, giving mine production and new equipment installed at mines, with accidents in the district in tabulated form].—State Mg. Bur. Report; pp 112.

— *New South Wales in 1915*. [Reviews the production of metals in the country].—Mg. Jnl. Sept. 2 1916; p 596; pp 2; 35c.

— *Pipe-Line Transportation of Petroleum*. [Full financial, cost, construction and operation accounts of various pipe lines in U. S. are given].—U. S. Federal Trade Commission Report; pp 467*.

Accounts and Bookkeeping

Young, George J.—*Elements of Mining*. [In an elementary way each different operation and department of mining is taken up such as haulage, prospecting, blasting, drilling, etc.].—McGraw-Hill; books; pp 628*; \$5.

Mining Costs

Green, Ravul.—*Actual Costs of Mine Haulage by Horses and by Compressed Air*. [Abst. from the Canadian Mg. Inst. Bulletin. In the comparison detailed costs are given].—Comp. Air Sept. 1916; p 8116; pp 2; 20c.

Reifsneider, L. B.—*Underground Mining in Cuba*. [A method which does not interfere with operations above in surface mining. The stopes are filled after being worked out].—E. & M. J. Sept. 16 1916; p 509; pp 2¾*; 25c.

Tillson, B. F.—*Hammer Drill Records at the Franklin Mines, New Jersey*. [From a paper read before the A. I. M.

E. Results obtained in drifting, stoping, raising, etc., are given, with costs].—Comp. Air Sept. 1916; p 8123; pp 2¾; 20c.

— *Iowa State Mine Inspectors' Report for the Biennial Period Ending Dec. 31, 1915*. [Reviews operations by counties, giving mine production and new equipment installed at mines, with accidents in the district in tabulated form].—State Mg. Bur. Report; pp 112.

Mining Miscellany

Eaton, S. Ford.—*Driving a 1200-Ft. Raise*. [A 10 by 20-ft. raise advancing at from 68 to 128 ft. per month. Methods employed and reasons for using the same are given].—E. & M. J. Sept. 9 1916; p 461; pp 3¾*; 25c.

Miller, Benjamin Le Roy; Singewald, Joseph T., Jr.—*Some Impressions of the Mining Industry in South America*.—Teniente Topics June 1916; p 11; pp 2¾; 35c.

Reifsneider, L. B.—*Underground Mining in Cuba*. [A method which does not interfere with operations above in surface mining. The stopes are filled after being worked out].—E. & M. J. Sept. 16 1916; p 509; pp 2¾*; 25c.

MILL AND MILLING**Sampling**

Young, George J.—*The Selection of a Method for Ore Treatment*. [On methods of testing and investigating new ores for refining treatment].—Met. & Chem. Engg. Sept. 15 1916; p 297; pp 2¾; 35c.

Crushing, Grinding, Etc.

Young, George J.—*The Selection of a Method for Ore Treatment*. [On methods of testing and investigating new ores for refining treatment].—Met. & Chem. Engg. Sept. 15 1916; p 297; pp 2¾; 35c.

Flotation

Belchic, George; Neal, Roy O.—*Surface Tension of Oil-Water Emulsions—A Flotation Theory*. [The surface tension of emulsions acid, alkaline and neutral are given for varying amounts of different kinds of oils as determined by the capillary method].—Mg. World Sept. 16 1916; p 487; pp 3*; 10c.

Gregory, S.—*Agreement Between Minerals Separation and the Inspiration-Anaconda Companies*. [Gives the final conclusions arrived at as a result of the lawsuit in regard to flotation equipment].—M. & S. P. Sept. 16 1916; p 424; pp 2; 20c.

Parmelee, H. C.—*Recent Developments in Zinc Concentration Practice in the Joplin District, Missouri*. [Details of results on the jigging and table methods now used. The possibilities of flotation are also reviewed].—Met. & Chem. Engg. Sept. 15 1916; p 319; pp 2¾; 35c.

Pearce, Jackson A.—*Flotation Tribulations*. [The results of operations and investigations made in the Idaho Springs district, Colorado].—M. & S. P. Sept. 16 1916; p 427; pp 4*; 20c.

Concentration: Sorting, Sizing, Washing

Dunstan, B.—*Queensland Mineral Deposits, Australia*. [A detailed description of nature of occurrence, production, prospects and methods of concentration of asbestos ores].—Queen. Govt. Mg. Jnl. Aug. 15 1916; p 372; pp 3½*; 35c.

Parmelee, H. C.—*Recent Developments in Zinc Concentration Practice in the Joplin District, Missouri*. [Details of results on the jigging and table methods

now used. The possibilities of flotation are also reviewed].—Met. & Chem. Engg. Sept. 15 1916; p 319; pp 2¾; 35c.

Robinson, Heath M.—*The Ozokerite Field in Central Utah*. [Abst. from a U. S. G. S. bulletin. Genesis, properties, production, concentration, etc., are considered].—Mg. World Sept. 16 1916; p 497; pp 1¾*; 10c.

Rossman, L. A.—*Nashwauk Iron-Washing Plants*. [Describes a small plant for washing and concentrating high-silica ores. Hydraulic principals are used in the machines].—E. & M. J. Sept. 16 1916; p 491; pp 2¾*; 25c.

Difference in domestic and foreign prices explained by the fact that the New York quotations are per fine ounce; the London per standard ounce 8.925 fine.

Copper.—Business in copper last week was very extensive, despite the fact that it was mostly from domestic users. Producers and dealers took orders for 50,000,000 to 75,000,000 lbs. Negotiations were continued on the new allied inquiry for 200,000,000 lbs. copper. Demand has shown no cessation. Consumers who first reckoned that they were playing a safe game by covering first quarter requirements have now come into the market for second quarter needs. Some users who were dilatory in ordering for the first quarter are now paying 1@1½ cts. more than they would have paid if they had heeded the warnings that a tremendous foreign order was pending.

It is really necessary to discuss the copper situation in superlatives rather than in current fact. The situation is almost to a stage where current business will be infinitesimal and still producers will be rushing smelters to capacity to fulfill their contractual obligations. Despite the strenuous efforts to increase refinery capacity the completion of additions has not added materially to the output. Over the month of September the actual refining capacity available was equal to a production of 175,000,000 lbs., but the important producers estimate the output at 165,000,000 lbs. Shortage of labor and inability to secure material for replacement of breakdowns are factors that cannot be overcome. Several plants in the west were closed for six days in September because of breakdowns and difficulty in securing parts. In the east three of the larger refiners had trouble in obtaining a full complement of workers. Thus, while it is probable that the new year will open with a refining capacity of 190,000,000 lbs. a month, it is not the belief of refiners that the output will reach that figure unless a startling change in labor and other conditions take place, developments that are not looked for.

Copper held very strongly at the advanced prices. Dealers and small resellers are cognizant of the inherent strength of the situation and are therefore less disposed to make concessions. Thus spot electrolytic sold at 29½ cts., while October and November sold at 28¾@29 cts. and December at 28½ cts. Producers had no metal this side of December, for which month they also took business at 28½ cts. Electrolytic for the first quarter sold at 27½ cts. and for the second quarter at 27 cts. Spot casting copper advanced to 27@27¼ cts., while for November producers of casting copper

asked 26¾ cts. and did not offer for December. Prime lake copper for November and December sold at 28½ cts. cash.

Some private foreign consumers have recently figured in the market for copper to be shipped in November and December, but the majority of the producers are unable to accept orders for this early delivery. Now that the details attendant upon the allied order have been settled it appears that munition production on the other side has been expanded remarkably to consume the amount of copper that has been purchased. There are some producers who believe that before the end of the first quarter of next year the allies will be in the market for another block of copper to supplement the purchase just made.

The London market advanced steadily in standard and electrolytic copper. Last week electrolytic advanced £3 10s to £140, while standard moved up £2 10s in spot and £2 in futures. The fortnightly statistics received Tuesday show the total visible supply in Europe to be 10,371 tons, as against 11,668 tons on Sept. 15.

Quotations for copper per pound in New York for the week ended Oct. 4 were as follows:

Tin.—Improved demand gave strength to the tin market last week, with sellers reporting a good turnover at higher prices. Large users were in the market for first quarter needs and quite a little covering was done in that direction, although at this writing sellers are less anxious to do business for the first quarter. Active absorption of the limits from the Straits acted to stimulate the eastern market and also that at London. The situation is gradually working towards a premium on futures over spot, a condition that the tin trade considers normal, but which has not prevailed in some time. The deliveries of tin in September amounted to 4025 tons, of which 3350 tons came from the Atlantic and 675 tons from the Pacific. The stocks and landing on Oct. 1 amounted to 4709 tons, this being a slight increase over the stocks and landing on Sept. 1. The deliveries are considered good, but the views as to the stocks and their effect on the market are varied. Straits tin on the spot advanced to 39½ cts., while spot Banka moved up to 38½ cts. Straits tin for November and December delivery sold at 39½ cts., while for the first quarter of next year business was done at 39¼ cts. Singapore advanced £2 15s to £177 last week, while Straits tin at London advanced £4 2s 6d to £175 10s.

Quotations for tin per pound at New York and per ton at London for the week ended Oct. 4 were as follows:

	New York		London.	Singapore.
	Spot.	October.	Straits, spot.	shipments.
Sept. 28	39¼c	39¼c	£174 12 6	£175 10 0

Lead.—Business in lead has continued on a good scale with the position of the metal very strong. Canada, Russia and Japan have placed large orders for October delivery and generally the situation is shaping for higher prices. The A. S. & R. Co. still adheres to its price of 7 cts. New York, but it is likely that an advance will be announced shortly. The producers are well sold up over October; in fact, some of them have no lead at all to sell for that month. Sales of about 5000 tons for export were noted last week. Domestic users have been actively covering needs over October. Independents did a good business for October at 7.10 cts. New York. Spot lots, which are very scarce, sold up to 7.25 cts., New York dealers being the sellers. For November delivery sellers are quoting 7.05 cts. New York and in some cases 7 cts. New York. The month of September was the best that the lead trade has had for a long time and the strength of the market is such that even the haphazard selling methods of some of the producers who have recently taken over the sales end of the business will not be likely to affect the market. Canadian ammunition makers have evidently taken some extensive contracts, as their inquiries for November and December lead are large. London advanced £1 5s in spot and £1 in futures last week, but has been easier this week.

Quotations for lead per pound at New York and per ton at London for the week ended Oct. 4 were as follows:

	New York		London	
	Indpts.	A. S. & R. Co.	Spot.	Futures.

Lead Ore.—The production for the week ending Sept. 30 was about the same as during the previous week, prices were slightly down and the majority of the ores sold at \$74 per ton, though some few lots went at as high as \$76. The week's production in the Missouri-Kansas-Oklahoma district was 1,524,845 lbs. and the year's production to date was 77,797,107 lbs. These amounts had respective values of \$55,010 and \$3,242,021.

Zinc Ore.—In the Missouri-Kansas-Oklahoma district during the week ended Sept. 30, though prices remained at the same level at which they have been for the past number of weeks, namely \$65 to \$45, sales were much larger and the ore seemed to be more in demand. The production during the week was announced at 13,969,700 lbs. and the total for the year at 492,856,820 lbs. The week's and year's production was valued at \$895,638 and \$21,234,440.

Calamine.—The largest production during the week came from the Aurora camp and the demand for the ore remained fairly firm at from \$40 to \$45. The production for the week of 1,682,895 lbs. was some higher than during the previous week and was valued at \$27,993. The year's production to date was 24,917,130 lbs., valued at \$802,673.

Spelter.—Speculative buying of spelter by large dealers has furnished the bulk of the recent activity in this metal. Dealers believe that spelter at present prices represents a very profitable purchase, figuring that consumers who are neglecting to cover will readily pay higher prices when they enter the market. Dealers have bought heavily for last quarter and first quarter deliveries. To a certain extent the tremendous copper business is regarded as assuring an active and large

demand for spelter. Spot prime western advanced to 9.45 cts. New York and 9¼ cts. St. Louis, while brass special sold at 10¾@11 cts. St. Louis for spot. Prime western for the fourth quarter sold at 9½ cts. St. Louis, but prices were advanced to 9¼ cts. St. Louis. For the first quarter business at first was done at 9 cts. St. Louis, but on the continued buying producers advanced their quotation an eighth cent. A few foreign orders for brass special and higher grades were noted. Consumers, as previously noted, are not inclined to purchase spelter for forward delivery. They feel that the metal has little chance of advancing sharply, but dealers by their actions in taking round lots, are giving vent to a belief that higher prices will prevail. The London market has been a nominal affair, the prices remaining at £52 for spot and £46 for futures for a number of days.

Quotations for spelter per pound at New York and per ton at London for the week ended Oct. 4 were as follows:

		New York		London	
		Spot		Spot	Futures

Year				13.914*		66.959

*For the first nine months; spot market nominal thereafter.

MISCELLANEOUS METALS.

Quicksilver.—Scarcity of supplies and an improved demand have resulted in an advance in quicksilver selling, agents putting the price up \$2 a flask to \$77 per flask. Some domestic users have had great difficulty in securing spot lots. Powder makers have been in the market for forward supplies.

Antimony.—Dullness continues with prices shaded to 11 cts. for spot. Chinese importers are striving to curb the reaction, but domestic producers are stimulating orders by concessions.

Aluminum.—There has been a fair demand for aluminum, but sellers as a rule report that the amount of business done is unsatisfactory. Prices are nominally unchanged and it is felt that concessions could be obtained. No. 1 virgin ingots are quoted at 61@63 cts. per lb. in carload lots, while No. 1 remelted is held at 59@61 cts. and No. 12 alloy at 47@49 cts. Sheet aluminum for prompt shipment is quoted at \$85@100 per 100 lbs. in the outside market, while 1917 contracts are quoted at \$40.

Sheet Lead.—Makers of explosives have been active buyers of sheet lead and prices have again been advanced a quarter cent, full lead sheets going up to 9 cts. f. o. b. mill and cut sheets to 9.25 cts. f. o. b. mill.

Zinc Sheets.—Leading makers continue to quote 15 cts. base for zinc sheets. Demand is quite active and the recent activity in spelter may be the basis for higher prices on sheets.

Platinum.—An advance of \$5.00 an ounce has been made in platinum by leading refiners, hard platinum being advanced to \$91 an ounce and soft to \$96 an ounce.

Pig Iron.—Activity in steel making grades of pig iron continues unabated, while foundry grades are becoming more active with higher prices. The average price on Bessemer iron in September was \$21.9346, as against \$21 in August,

while the basic iron average was \$18.63, against \$18 in August. Sales of basic iron have been made at \$19 valley, while bessemer has sold at \$22 valley, these prices now being the minimums. Foundry iron prices have gone up 50 cts. to 75 cts. in various districts.

Ferromanganese.—English makers continue to quote \$165 seaboard for 80% ferromanganese, but have taken no business, although domestic producers who are quoting the same price have secured some sizable orders. The growing popularity of domestic ferromanganese is a cause of concern to English makers and further price concessions may soon appear.

No. 16. Vol. 45.

CHICAGO

October 14, 1916.

Pinos Altos District, Grant County, New Mexico

CLIFFORD C. BLOOD.

Grant county, New Mexico, produces more kinds of minerals than any district in the southwest. Copper, gold, silver, zinc, lead, manganese and many others in smaller quantities are listed in the output. More copper and more silver is shipped from this county than any in the state. The recent sales of the Carlisle mines in the Steeplecock district, the Austin group in the Burro mountains and the Silver Cell in the Pinos Altos mountains are examples of the activity. The town of Pinos Altos, almost in the center of the district from which it takes its name, is 9 miles from

the earliest ranches in the county were those now incorporated in the holdings of the Silver Cell Mining Co. Early in the 80s the Dimmicks acquired title to the property. Clinton Dimmick, while herding cattle just outside the ranch property, one day picked up a slab of rock which was very heavy. Taking it home he and his brother made an examination and found it full of native silver. The Dimmicks worked the property themselves, sinking on the site of the first discovery, and although there has been several lessees of the property they steadfastly refused to let it go until

HOIST AND POWER PLANT, SILVER CELL.

THE SILVER CELL PROPERTY.

Silver City, northwest. The Chino Copper Co.'s Santa Rita mines are northeast, and the Phelps-Dodge Burro mountain holdings are southeast. Unique is the Pinos Altos district in that although surrounded by some of the richest copper mines in the country, there is little copper found in its confines. Still more unique is the Silver Cell property, when it is understood that the Pinos Altos district being primarily a gold district, yet the Silver Cell is almost totally high-grade silver. It is a mile south of Pinos Altos and 8 miles from the railroad at Silver City.

Pinos Altos was the first county seat of Grant county before its more prosperous neighbor took that honor, and in the early days played no inconsiderable part in the affairs of this part of the state. Two of

this year, when they sold their holdings to the present owners.

The property includes six patented claims, known as the Silver Cell group and comprising the Silver Cell, Climax, Mangus, Keystone, Black Terrier and Wedge. They were surveyed on Feb. 14, 1900, by Charles E. Chester. The two patented homesteads of 160 acres each, joining the group of claims, and themselves highly mineralized, make the property 440 acres in extent.

The region is probably of Archaean era, being a complex of highly metamorphic rocks containing feldspar, with a sort of hornblende schist regularly intruded in diorite granite. It is of granite porphyry formation. Dikes containing quantities of iron py-

rites range through the district in a general northeast-southwest direction. The ore veins follow the guidance almost parallel to the porphyry. Ligulas of granite thrust into the metamorphics is a feature of contacts. There are evidences, though not conclusive, of an early glacial period. West of this district there seems no accounting for the surface conditions except by the theory of an early river bed in Mesozoic or even Paleozoic age. This is not substantiated.

The veins, though not of the latest structural period, are probably of the Tertiary age. They are well defined in places and in others almost hidden. One of two reasons must account for the station, either the fact of an earlier glacial period, or a formation not later than the Tertiary. They vary in width on the surface from mere rays to 2 ft. and widen greatly with depth. Both the hanging and the foot walls are granite porphyry, the foot wall frequently gneissoid. No replacement of the wall rock is noticeable and careful tests have found no value outside the regular course of the vein matter.

The Various Ores.

Silver in native state, locally known as wire silver, occurs in vugs, breccias and chimneys, the latter much more numerous. Huge lumps are usual. The chimneys persist with depth and generally follow the mode of the veins in widening. Slabs of almost pure metal varying in width from a half-centimeter to 6 centimeters are sometimes found contiguous to the foot wall and conterminous to the eruptive. This is also found permeated through the whole fissure to a greater or less extent. The aggregation found in vugs ranges around 90% actual weight in silver.

Native silver sulphide, commonly called silver glance, is the second ore of value on the property for 300 ft. under the surface. It has a dark, lead-gray color and bright metallic lustre. It is always intermixed with the wire silver, with cones and cemented breccias of white and dark granite, flint and spar intruded with the ore. It is a very perseverent formation and distressing to the driller.

Pyrargyrite is a dark red silver ore, known as Ruby silver, a sulphide of antimony and silver, and is the value-giving ore of the property. On the 400 level pyrargyrite is seen easily to carry the value of the workings. This ore is reputed never to be found except in true fissure veins.

Proustite is a cochineal red or scarlet variety, being a sulphide of arsenic and silver. It is found in quantities.

Stromeyerite, sulphide of silver and copper, carries almost the only copper found on the property. It has a metallic lustre, comes in compact masses, and is steel gray to greenish in color. Only a few times has any of this valuable ore been recognized.

Stephanite is a combination of silver, antimony and sulphur, is an iron-black orthohombic mineral, commonly called brittle silver because of its propensity to crumble. On this property stephanite con-

tains so much sulphur as to change its color to yellow and is confounded with iron pyrite by those not familiar with the district. It is found in large masses in certain portions where the fissures widen.

Sternbergite is a sulphide of silver and iron, dark brown in color, and found in tabular crystals and laminae: remote from pyrargyrite, but near the argentite and free silver.

Cerargyrite, native silver chloride, or, as it is generally known, horn silver, is found in large quantities west of a certain wide porphyry dike which cuts through a corner of the property. It is white to pale yellow in color, but darkens on exposure to light.

Tellurides and bromides are not found. Some gold is washed in the canyons and in creek beds, color being found all over the property. Assays in the silver veins have found values from 50 cts. to several dollars, there being more gold value on the 400 level

200-FT. SHAFT ON SILVER CELL.

than nearer the surface. So far no attention has been paid to any gold found.

The veins are true fissures, probably several thousand feet in depth. At the 450 level on the Silver Cell vein, there is no evidence of it pinching out, but on the contrary is almost twice the width as on the surface. Every indication points to great depth.

I have tried in this short article to give a comprehensive perception of the Pinos Altos district in general, and the Silver Cell property in particular.

The Silver Cell Mining Co. is capitalized at \$300,000, par value \$1 per share. The present majority stockholders own three-quarters of the entire property, which they bought from the Dimmicks. The present officers and directors are: Tragedias de la Peña, president; Oscar Franke, vice-president; Hilario Losoya, secretary-treasurer and general manager.

Don Señor de la Peña is ex-governor of Sonora, and was one of the most influential factors in the old regime of Mexico, having held several cabinet positions as well. Oscar Franke is a son-in-law of Señor Peña, and is a mining man of high ability. Don Hilario Losoya is ex-governor of Durango, and a member of the Losoya family in that state.

Separating Metals from Flue and Bag House Dust

Metals such as bismuth and tellurium and cadmium are often contained in flue and bag house dust in sufficient quantities to pay to reclaim them. A process developed by R. H. Stevens, Salt Lake, Utah, for doing this, as well as separating the arsenic acid contained in the materials treated from cadmium, has been assigned to the U. S. Smelting, Refining & Mining Co. The diagram herewith shows the component parts of the process in their proper relation.

The ore, furnace products, flue or bag house dust is first roasted to a dead roast for the purpose of converting all cadmium sulphide into cadmium oxide, of volatilizing all volatile arsenic compounds, and of converting all non-volatile arsenic compounds into their corresponding arsenic acid compounds. The material is then ground or pulverized to any desired mesh. The pulverized material is then placed in a solution tank.

Dilute sulphuric acid is run into the tank and the solution and material are agitated until all the available sulphuric acid is consumed. The solution is then drawn off into containers. The material is treated with fresh dilute sulphuric acid one or more times to dissolve more of the cadmium. To dissolve the remaining cadmium, the material is then treated with a stronger solution of hot sulphuric acid. This strong acid is drained off and used for making weaker acid for treating fresh material. The material is finally washed with water. This water is usually added to the strong acid solution for diluting it to the proper strength for treating fresh material.

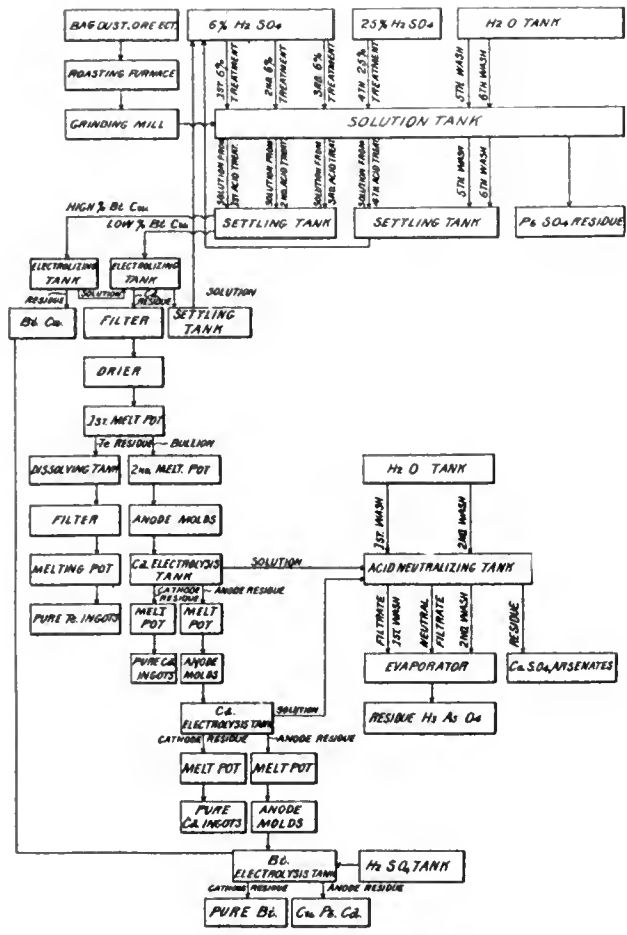

The clear solution containing the cadmium is led into electrolyzing tanks. If the solution contains any considerable amount of copper, bismuth, tellurium and the like, it is electrolyzed at a voltage preferably from 1.8 to 2.1 volts until most of the bismuth and copper are deposited on the cathodes, leaving the cadmium in the solution. The sulphuric acid solution obtained by treating the ground material with sulphuric acid, or in case copper, bismuth, tellurium and the like are present, the same sulphuric acid solution, after it has been electrolyzed to remove these metals, is led into an electrolyzing tank or tanks which are provided with easily removable false bottoms. The electrolysis is carried on at a voltage from 2.2 to 3.4 with a current density of from .01 to .05 ampere per square inch until the cadmium is deposited from the solution.

The cadmium will be deposited upon the cathode in a coherent form, or will be partially deposited on the cathode in a coherent form and partially fall from the cathode in a non-coherent form to the false bottom, or practically all fall from the cathode in a non-coherent form to the bottom, depending upon the composition of the solution.

The solution resulting from the cadmium electrolysis is treated for the separation of the arsenic acid contained in it. The cadmium from the cathode

or from the false bottom or both is filter-pressed and dried, after which it is melted under dry sodium hydroxide and powdered charcoal at a temperature of about 400 degrees centigrade. The arsenic and tellurium which may be present with the cadmium are dissolved in the fused sodium hydroxide. The flux formed by the sodium hydroxide and the tellurium and arsenic is dissolved in water and a current of air is blown through the solution, which causes the tellurium to be precipitated in a metallic state. The precipitate is washed, dried and cast for marketing.

The cadmium bullion which is drawn off from be-

STEVENS PROCESS TREATING FLUE AND BAG-HOUSE DUST.

neath the sodium hydroxide flux is cast into anode plates preparatory to a further electrolytic purification. Metallic copper or metallic cadmium plates are used as cathodes, and the electrolysis is carried on in a solution of cadmium sulphate, sulphuric acid and a soluble salt of sulphocyanic acid, preferably an alkaline sulphocyanate. The solution is electrolyzed at approximately 0.4 volt with a current density at approximately five amperes per square foot.

The solution is preferably agitated during electrolysis so that a coherent coating of cadmium is formed on the cathode. By this process, pure cadmium is deposited on the anode, while copper, bismuth

and lead which may be contained in the impure cadmium bullion remain in the anode sludge.

The sulphocyanate prevents the copper from going into solution with little or no consumption of the sulphocyanate. The lead is prevented from going into solution by the sulphuric acid. The solution must contain a small amount of free sulphuric acid or the cadmium will not be deposited on the cathode in a coherent form.

The acidity of the solution is preferably maintained by placing in each end of the electrolyzing tank an insoluble anode and a copper or cadmium cathode. These electrodes are connected to an independent circuit of about 2.5 volts in which the current is regulated so that sufficient cadmium will be precipitated to maintain the proper acidity of the solution.

Some provision must be made to maintain the proper acidity, because more cadmium is dissolved at the cadmium bullion anodes than is required by the

electric current. The refined cadmium deposited on the cathodes is melted under sodium hydroxide or paraffin and cast for marketing. The anode sludge contains quite a proportion of cadmium so that it is remelted and cast into anode plates, and more of the cadmium is electrolytically refined.

The sludge resulting from the second refining process will be comparatively low in cadmium and high in copper, bismuth and lead. To separate the bismuth, this sludge is again remelted and cast into anode plates and is electrolyzed in a bath of bismuth sulphate, sulphuric acid, and a soluble salt of sulphocyanic acid, preferably an alkaline sulphocyanate, together with sufficient glycerol to clarify the solution. The remelted sludge forms the anode, and a metallic copper plate forms the cathode. The electrolysis is carried on at a voltage of about 0.4 volt at a current of approximately three amperes per square foot. The bismuth is deposited in a pure state at the cathode.

The Present and Future Supremacy of Metals.

Kirby Thomas, of New York, consulting mining engineer for some of the largest metal mining companies in the country, was in Chicago this week, and in an interview insists that the greatest problem that confronts the mining men of America today is that of present and future world supremacy.

"Before the war," said Mr. Thomas, "prices were made for us by Germany. Today England is trying to assume the control which lapsed at the beginning of the war. Temporarily prices are being made in this country, and the problem that confronts us is how to retain that control of world metal markets after the war. And that is the question which I hope will receive the careful consideration of the American Mining Congress when it meets in Chicago in November.

"It is a critical period in the mining industry, for today the industry is confronted with the problem of expansion incident to phenomenal prices—war prices, and a unique and irregular market, due also to the war. I say 'unique and irregular' because the warring countries pay us phenomenal prices one day and on the next day they want no more of the product. It is a case of prices moving up and down, and rapidly, at that. Then, too, the political aspect of the mining industry is vitally affected by the prospect of the foreign trade horizon of the United States, which means an acute problem after the war. With these fundamental factors at work the industry had to meet wage increase and increase in cost of material by improved processes, by better equipment, by decided improvement in mining efficiency.

"So you see that the questions which will come for solution before the American Mining Congress are broad and fundamental. No session ever held is, in my opinion, quite as important as will be this one at Chicago. And the most important problem of all is the question of control of the metal market. Are

we going to change from Germany to England? Will England be a more trying master than was Germany? And why, pray, change masters? Why, indeed!

"We can and we must be a world power in the mining industry. Clinging to this problem like a Siamese twin is that other question, 'What's going to happen to American mining interests abroad, in Mexico, in Canada, in Colombia, in Peru, in Chile?' Ask Washington.

"Today three-quarters of the mining engineering heads of the world come from England and America—and America leads England in this respect. Why, Russia has been calling for them as fast as they crop up. I just sent a man to Peru and another to Brazil.

"I asked this question: Should we be confined to sending out only our brains and keep our money at home. It depends on Washington. Protection of American capital invested abroad is what is needed. Capital is, as you know, timid. It will not go where it does not feel secure, where there is the slightest doubt about its return. When it goes out it wants not alone a 'God-speed-you' but an 'Au Revoir' from its own government. That is what English capital gets when it goes abroad. Of course, talent is never timid. Brains go where there is the greatest demand for them and the best pay. But what does that little return in payment for brains amount to compared to the enormous returns that come from the free and protected investment of millions upon millions in capital.

"And another fundamental problem which I will not discuss in detail is the tariff need of the mining industry.

"But above and beyond all I hope the Congress will discuss as comprehensively and thoroughly as possible the problem of building for the future upon the present abnormal demands for metal."

Gypsum and Lime Industry in Central Montana

O. W. FREEMAN.

Montana possesses pure and very extensive gypsum, lime and clay deposits, but has always been of minor importance in the production of gypsum, lime and cement products. The output has not been stimulated by the great markets close to those states leading in the production of these substances, but now with the increase in the demand from the northwest, the great reserves of plaster and construction materials in Montana will be utilized in increasing amounts.

A small gypsum mill was operated for several years in southern Montana at Bridger, near Red Lodge, in Carbon county; but being several miles from a railroad could not produce and ship plaster of paris very cheaply and has been closed for some time. Another mill was operated successfully near Arming-ton, southeast of Great Falls, for several years, on a gypsum deposit 25 to 30 ft. thick, but this mill has

The South Moccasin mountains are a small group in central Fergus county; about a mile south of them a dome uplift has occurred, probably the result of an igneous intrusion, and the overlying Cretaceous shales and sandstones have been removed by erosion, exposing the gypsum-bearing Jurassic strata. Spring creek has cut a valley through the southern part of this dome and both the great Northern and the Chicago, Milwaukee & St. Paul railroads have here built along the north side of the valley, their tracks coming within 50 yds. of the gypsum outcrops. Spur tracks have been completed and the shipping facilities are excellent.

The Hanover Gypsum Co. owned about 1000 acres on this dome, most of which is believed to be underlain by gypsum. Gypsum outcrops a few rods from the mill. The top bed is 7 to 11 ft. thick, and has been

HANOVER GYPSUM CO.'S MILL NEAR LEWISTOWN.

25-FT. GYPSUM OUTCROP IN MONTANA.

also been closed for several years. Near Great Falls a small mill of about 100-ton capacity has been operated for some time past, and until this summer was the only mill in operation in the state. Some gypsum has been quarried and shipped from Limespur in Jefferson county. Recently the Hanover Gypsum Co. has built a 400-ton modern plant on its property, 7 miles west of Lewistown, in central Montana, which is now the largest in the state.

Gypsum occurs in central Montana in two ways. First as selenite crystals disseminated throughout the black Bearpaw and Claggett shales of Cretaceous age; these crystals are of many different sizes and forms and are often twinned, and while abundant in the bad lands where erosion has carried away the shales in which they are found, are of no commercial importance. Second, as beds of gypsum rock and of disintegrated gypsum, or gypsite, which are the source of the commercial products. The age of the chief gypsum beds is believed to be Jurassic, and they were probably the result of evaporation of sea water, and consequent deposition of the gypsum from solution. Some gypsum beds, however, are late carboniferous, possibly in part Permian or Triassic.

disintegrated to form gypsite, which is either at the surface, or under slight cover, and will be worked by quarry methods. This bed is underlain by a few feet of limestone, which in turn is underlain by a bed of pure white gypsum 15 to 30 ft. thick, which will be mined, the limestone affording a good roof. Both the main quarry and the mine are about 1000 ft. from the mill, and the rock from them is loaded on the same track, which has a grade of $2\frac{1}{2}\%$, and is carried to the mill by gravity; mining costs should then be low. A third gypsum bed underlies the others, but it has not been explored much by drilling, and will not be mined at present. In summer the gypsum will come entirely from the quarry, but in winter much of it will be mined.

In the mill the gypsum first passes into a 24 by 36 Ehram jaw crusher that has a capacity of 1 ton per minute, and crushes the material to a 4-in. size. A rotary crusher of equal capacity next reduces this to a 1-in. size, after which it goes to the storage bins. The crusher building is separate from the rest of the mill, and an underground conveying belt carries the crushed gypsum from the bins, first over a rotary drier and then through a cylindrical drier 6 ft. in

diameter and 40 ft. long. The dried gypsum is then elevated to bins, from which it next goes to the Raymond pulverizing mill, which grinds it into a fine powder. It is then lifted by a Cyclone elevator and blown into the large calcining kettles, where most of the water of crystallization is driven off, thereby changing the gypsum into stucco or plaster of paris.

Besides various manufactured plasters, made by mixing with hair or fibre, the company makes plaster board, land plaster, gypsum tile and crushed gypsum for use as a retarder in Portland cement. The mill has a present capacity of 300 to 400 tons daily, but there is room for more calcining kettles, and by their installation the capacity of the mill could be easily doubled, as the capacity of the rest of the machinery is in excess of present requirements. About 30 men are employed at the plant, which represents an investment of about \$150,000. The Hanover gypsum is exceptionally pure and many carloads of crude have been shipped to other companies who wish to increase the percent of their product.

The company's property, after only a few days' operation, was sold the last of July, 1916, to Charles Boettcher and associates, who control the Three Forks Portland Cement Co. This concern is at present operating the sole cement plant in Montana, at Trident, a few miles from Three Forks. It is the intention to start work very soon on a new cement plant at Hanover, near Lewistown, which will cost approximately \$1,000,000.

Limestone outcrops in the South Moccasin mountains less than 2 miles away and is so situated that quarrying will be cheap and easy; transportation will be by tramway, and surveys have already been made. Very extensive beds of Cretaceous shales are also found within a short distance of the plant. With these favorable factors cement should be manufactured at a reasonable cost. Railroad extensions east from Lewistown are now being constructed, which will enable the new plant to supply plaster and cement to the Dakotas, as well as northern and eastern Montana.

The United States Gypsum Co. has just announced that it will immediately start work on a gypsum plant of several hundred tons daily capacity at Heath, about 10 miles east of Lewistown. Three hundred acres have been leased which contain exceptionally pure gypsum. It is estimated there is at least 7,000,000 tons easily available on this tract. Two miles south of Forest Grove pure thick beds of gypsum outcrop extensively. The Chicago, Milwaukee & St. Paul branch east from Lewistown passes close to both these deposits. Pure beds of gypsum outcrop extensively. The Chicago, Milwaukee & St. Paul branch east from Lewistown passes close to both these deposits. Pure beds of gypsum over 20 ft. in thickness occur in the foothills of the Big Snowy mountains, as on the East Fork of Spring creek, and near Irene, on the south side of the Snowies. A small amount of pure white gypsum has been produced in the foothills southeast of Moore,

but practically no work has been done on any gypsum deposits near the Big Snowy mountains. The gypsum found on the southwest side of the Snowies is exceptionally white and pure, and being found only a few miles from the railroad, might be utilized at a profit. Quantities of excellent gypsum in beds 20 to 30 ft. thick occur on Alaska Bench, east of the Snowies and near the N Ranch, northwest of Tyler. These deposits are, however, a long way from the railroad. They both appear to be of Upper Carboniferous age. Northwest of the Little Belt mountains a great gypsum bed outcrops where Jurassic rocks occur; this bed is very thick and pure, as near Kibbey, 30 miles from Great Falls. Farther south, to the southwest of the Little Belts, the gypsum beds become thin and impure. Large deposits of gypsum also occur in eastern Montana, and north of the Missouri river near the Bearpaw mountains and elsewhere. With such large reserves available, the manufacture of gypsum products in the near future will probably be restricted chiefly to those localities where railroads are close to the gypsum properties, the more important of which have been briefly mentioned.

The major part of the Little Belt and Big Snowy mountains in central Montana are composed of limestone, varying in composition from a dolomite to a very pure limestone, free from magnesium. A very considerable part of the nearby Judith, North Moccasin, South Moccasin and Little Rocky mountains are also composed of limestone. Limestone is found in easily accessible and inexhaustible quantities. The limestone is chiefly of Carboniferous age, and being harder than the soft overlying sandstones and shales, it outcrops in prominent cliffs that in most cases rise abruptly from the plains. Quarrying is cheap and simple, and where found near railroads, as in the Little Belts and South Moccasins, might be sold at a profit to the smelters for flux. The plains about the mountains are chiefly composed of Mesozoic and Tertiary formations, which are largely composed of shale, much of which would make good brick and cement materials. As in the case of gypsum, however, there is so much lime and clay that their utilization depends more on convenience to railroads than on the extent of the deposits themselves. Considerable lime formerly was burnt in small home-made kilns, especially in the Judith mountains, but after the advent of the railroad these small producers were unable to compete with foreign producers and were gradually abandoned. A modern limekiln should prove successful, and would be able to cheaply supply the nearby markets. Only a little lime, as near Helena, is made in Montana at present. Over 300 billion tons of coal, varying from lignite to bituminous, are found in central and eastern Montana, so fuel will always be cheap and plentiful. Electric power, mostly generated at Great Falls, can also be secured at reasonable rates.

Central Montana contains such large deposits of easily worked clay, gypsum and limestone, that there is no question but that with the increasing settlement

of the northwest several gypsum, lime and cement plants will be started to supply at least the local demands for such construction materials. There is also little question but that, barring accidents, their operation should prove commercially profitable.

Sizing and Classifying Ores.

Three important features are embodied in a new type of sizing machine.

(1) The sizing units are independently operated and adjustable.

(2) The sizing surfaces consist of a number of separate units, each unit doing only a portion of the sizing, and the last one in the series completing the operation and separately delivering the sized products.

(3) Means for transferring the particles from one sizing surface to the next succeeding one in ap-

A NEW ORE SIZER AND CLASSIFIER.

proximately the same condition in which they left the surface, and at a higher point on the next succeeding surface than would be the case were the particles allowed to take their natural path of travel from one sizing surface to the next. It was found by experimenting that when extremely close sizing is required, for instance, such as is necessary to prepare certain kinds of ore pulp for the separation of their various constituents upon the usual form of concentrating or separating units, that the sizing can be better accomplished on a number of separate units, as each unit acts upon the material independent of the other, and the speed of the moving deck, its speed of vibration and its inclination can be independently controlled, thus obtaining a closer and more accurate adjustment for the work to be accomplished.

The device which carries out these ideas has been patented by H. M. Sutton and W. L. and E. G. Steele, all of Dallas, Tex. The accompanying illustration shows the method of operation, where the general trend of the ore stream is clearly defined. The aprons not only revolve but are vibrated at the same time, and, being on an incline, the coarser, heavier particles tend to move toward the lower side.

At the edges of the deck frames toward which apron travels are deflecting baffles so disposed as to receive and deliver the sized particles from one sizing surface to the next lower one in a manner to prevent their racing or bouncing.

U. S. Bureau of Mines Publications.

The following bulletins have been issued by the U. S. Bureau of Mines:

Bulletin 105. Black damp in mines, by G. A. Burrell, I. W. Robertson, and G. G. Oberfell. 1916. 92 pp.

Bulletin 116. Methods of sampling delivered coal, and specifications for the purchase of coal for the Government, by G. S. Pope. 1916. 64 pp., 5 pls., 2 figs.

The following technical papers have been issued:

Technical Paper 102. Health conservation at steel mills, by J. A. Watkins. 1916. 36 pp.

Technical Paper, 151. Coke-oven accidents in the United States during the calendar year 1915, compiled by A. H. Fay. 1916. 18 pp.

Technical Paper 159. Production of explosives in the United States during the calendar year 1915, with notes on coal-mine accidents due to explosives, and list of permissible explosives, lamps, and motors tested prior to June 1, 1916, compiled by A. H. Fay. 1916. 24 pp.

Technical Paper 161. Construction and operation of a single-tube cracking furnace for making gasoline, by C. P. Bowie. 1916. 16 pp., 10 pls.

Illinois Methods of Preparing Bituminous Coal.

An extensive study of the methods employed in the preparation of bituminous coal at Illinois mines has been made by the Engineering Experiment Station of the University of Illinois. The data and information which have required several years to compile have been tabulated and analyzed by Professor E. A. Holbrook and are now published as Bulletin 88 of the Engineering Experiment Station.

The results are subdivided into (a) Evolution of present preparation practice, (b) standard types of tipples or preparation plants, (c) impurities and breakage of coal, making preparation necessary, (d) sizing and sizes of Illinois coal.

A record is presented of the yearly production of the different sizes of coal in Illinois over a period of 35 years, agreements between operators and miners as affecting preparation are discussed, and requirements for standardization are studied.

Nowadays in nearly all mines winzes and ore chutes in the floors of drifts are protected by gates to prevent men from falling into them.

A Cost Computer for Belt Slips.

Because of the fact that cost of belt slips is not given enough attention, this alignment chart has been devised which covers nearly every factory in the world in which all power developed is distributed to machines via belts. The vast majority of power plants for mills, shops and factories burn less than 10,000 tons of coal per year—the limit of the chart. The chart is built on the recognized rule: "Each per cent of belt slip costs 1% of the power." One per cent of the power, of course, represents approximately 1% of the coal pile. That is why the cost of coal and the cost of belt slip is so intimately linked.

For example, let us take a factory where the slip

COST CHART FOR BELT SLIPS.

of the main belt is 4%, and the slip of the smaller belts beyond the engine and main belt an additional 4%. The total slip is therefore 8%.

Let us further assume that 2000 tons of coal are burned per year in this factory, and that the cost of the coal is \$3 per ton. What is the cost of the belt slip per year? First join the \$3 (column A) with the 2000 tons (column E). Note the point of intersection in column D. Now join that point of intersection with the 8% slip (column B). The resulting cost is found at the intersection with column C and is \$480 per year.

These figures are not exaggerated in order to make them emphatic; \$480 per year is a serious enough loss to attract the attention of any factory, mill or other superintendent. There should be no slip at all. Slip is usually easy to stop. If it cannot be stopped there is something wrong with the design of the drive and alterations should be made.

The slip has not been carried beyond 10% because no factory would tolerate that amount, year in and year out. There is no question but that total slip

reaches and even passes 10% in many a plant, but it is usually noticeable, and after much squealing and running off, the belt is "fixed" in some way or other to reduce slip.

As will be noted, the limit of the chart is \$10,000. This would be the cost of belt slip where 10,000 tons of coal are burned per year; where coal costs \$10 per ton; where slip is 10%, and where all power is transmitted through belts. That, of course, would be an exaggerated case.

A straight edge may be used in computing with this chart, a rule or steel square, or anything else that is straight. A black thread is very handy, for when stretched tight a thread is straight, and as you can see on both side of the thread at once, it is quickly spotted in place.

Discovery of Lapis Lazuli—Important if True.

A unique and important discovery has just been made of lapis lazuli, or lazurite, about 100 miles west of El Paso, over the El Paso Southwestern railroad, in the northwestern part of Tres Hermanas (Three Sisters) mountains, 12 miles northwest of Columbus, in southern New Mexico. This is practically the first discovery of this rare and precious stone in quantity ever made in the United States, as only small deposits have been found in one other place in California. In this newly discovered vein there is believed to be an inexhaustible quantity of it, which can be mined from the very surface.

The discovery was made by W. J. Holmes, a mining man of El Paso, who, while operating a zinc mine in these mountains, chanced to notice some specimens in the cabin of an old negro prospector. Holmes, who had lived in San Francisco and had seen the lazurite rock in the famous lapidary of Kincaid that came from Russia, some 20 years ago, instantly recognized it and began prospecting for the vein, which he finally discovered last week.

The vein occurs in a fissure in granite, having a northwest-southeast strike, showing on the surface a width of 1 to 5 ft. and a strong outcrop of over 1000 ft. in length. Along the surface of the claim are large boulders of the rock scattered around, some of them weighing half a ton each, all of which are colored and banded or seamed with a beautiful blue color. Samples of the rock have been tested in the local assay offices and laboratories, and others have been polished, with the result that the rock is pronounced to be lapis lazuli. A claim has been located by Mr. Holmes, Claude A. Brown and Fred E. Cunningham of El Paso on the vein, which is named the Lapis-Lazuli Ultramarine mine. The owners are arranging to start development work at once.

The principal mineral products of Peru are copper, petroleum, coal and lead, their importance being in the order named.

Delaware Judge's Decision Favoring Minerals Separation, Ltd.

As mentioned in last week's issue of Mining and Engineering World, Judge Bradford of the U. S. District Court of Delaware has rendered a decision, in the suit of Minerals Separation, Ltd., vs. Miami Copper Co., favoring the plaintiff in two claims and holding invalid a third. Former attempts of the Minerals Separation, Ltd., to secure injunctions in western courts against the use of its process on the ground of infringement were unsuccessful.

We append an abstract of Judge Bradford's decision:

The court holds that "under the processes shown in the three patents a signal advance has been made in the art of ore concentration in point of simplicity, economy and efficiency and in their practice large commercial success has been realized." . . . He then cites other practices which, "however, were far from commercially successful, being wasteful of water, of power and of a considerable proportion of the metallic particles in the slimes which were carried up to the surface and were lost with the gangue.

"Without pausing at this point to consider other processes of ore concentration disclosed in the prior art hereinafter discussed an important and, indeed, vital difference between water or gravity concentration under such processes and concentration under the processes of the patents in the suit is that while in the former the metallic particles after being separated from the gangue in the ore pulp sank to the bottom, in the latter the metallic particles coated with an extremely thin film of oil became attached to air bubbles in the ore pulp and the bubbles with the attached metallic particles rise to the surface, forming a mineral froth of such coherency and permanency as to afford full opportunity for its removal from the surface for further treatment of the metallic particles. The ore pulp in the process of each and every one of the three patents in suit consists of a mixture of water and crushed or pulverized ore, together with one or more other ingredients.

"In each the agitation of the pulp coupled with the introduction of air into it develops and distributes throughout the mixture small bubbles of air which attach themselves to the metallic particles to the exclusion of the gangue and rise with them and form metallic air froth on the surface readily removable therefrom, the gangue particles sinking to the bottom and being disposed of as refuse."

Judge Bradford in his opinion says that "the first patent in suit is what is known as an air flotation process in which the frothing agent consists of an oil or other immiscible substance, or material of an oily nature and the bubbles and metallic particles become attached to each other through affinity between the bubbles and the metallic particles enhanced by the coating of the latter with an extremely thin film of oil. The old water processes of ore concentration were in some features gravely objectionable.

"Under those processes it was desirable to avoid very fine grinding of the ore as being calculated to cause the fine particles containing metal to escape with gangue particles and be lost. In these processes there were two things to be avoided: first, the crushing or grinding of ore to such a degree of fineness as to lead to the loss of metallic particles through their escape; and, secondly, too coarse crushing or grinding whereby particles of ore containing both metal and gangue might, with the gangue preponderating, too readily be carried to the surface and lost with the other gangue particles.

"The defendant admits that the air bubbles collect the metallic particles and the oil or other modifying agent in the mixture gives permanency to the mineral froth; that the attraction of the air bubbles for the metallic sulphide par-

ties leads to the separation of those particles from the gangue so that in the absence of oil or other modifying agents in the pulp facilitating the formation of air or other gas bubbles, no process of concentration employing such bubbles is possible. . . . But there is an accentuated difference of opinion between the parties on the point of preferential affinity of oil for metallic particles as compared with the gangue.

"One of the principal questions in the case is whether patentable invention was involved in the discovery that the minute proportion of 0.1% of oil to the ore was sufficient for commercially successful operations in ore concentration. On this question I had some doubt during presentation of the case. But this doubt has since been removed. . . . There was, I think, patentable invention in the discovery made in March, 1905. Prior to that time there had been no suggestion in the art that the proportion of 0.1% of oil to ore or any other fraction of 1% of oil to ore would or might result in successful concentration. The statutes provide for patenting new and useful inventions and discoveries, but a bare discovery unaccompanied by the exercise of any invention in utilizing or reducing it to practice would not justify or support a monopoly in the discovery. In the present case, however, the facts disclose not a bare discovery, but a discovery coupled with invention in usefully applying it. In such cases patents may properly be granted. The defendant lays stress upon the proposition that the reduction in the amount of oil in the process for the concentration of ore did not and could not involve patentable invention, but only an ascertainment of the proper degree in which oil should be used, which was readily discoverable by any one competent to conduct or superintend a process of ore concentration; and, further, that motives of economy would naturally have suggested a reduction in the quantity of oil to the extent of its excess over what was necessary for the accomplishment of the purposes of the process.

"But if such a reduction was obvious why is it that it was never made prior to the discovery in question. No one today understands how the use of only 0.1% of oil operates to secure the mineral froth of the first patent in suit. This is testified to by experts and admitted on both sides. . . . I perceive no escape from the conclusion that the discovery was patentable. To decrease the amount of oil used in an old process, so long as the characteristic mode of operation and result of such process are preserved, even though in less degree, does not as a general rule involve invention.

"The defendant contends that a substantial increase in the amount of oil involved used will not affect the nature or efficiency of the process of the separation, but will only add to the cost of carrying it on with an unnecessary amount of oil. But this position is in conflict with the decided weight of the evidence and with the showing of the experiments conducted by Higgins immediately prior to the time of discovery. It is satisfactorily proven that the process of first patent in suit depends upon the selective affinity of the air bubbles in the mixture for oil coated metallic particles, that the affinity is strongest when the film of oil surrounding the metallic particles is so thin as to be imperceptible to the senses, and that with any substantial increase in the quantity of oil on the metallic particles the character of the process is changed and its efficiency diminished for some reason as yet unrevealed.

"A great advance in the art of ore concentration has resulted from the process of the first patent in suit in efficient recovery of slimes. With the use of that process ore may be so finely ground as to insure the thorough separation of the metallic particles and gangue and great savings effected. The profit so saved in a single year from the output of the principal porphyry copper mines, including the defendant's, has been estimated by one of the expert witnesses as more than \$17,000,000.

"The defendant contends that there is nothing new in the employment of only a fraction of 1% of oil relative to the

weight of the ore in the process of the first patent in the suit. On the whole, I am satisfied that the first patent in suit must be sustained as to claims 1 and 12, but not as to claim 9. The two former are definite, specifying and limiting the amount of oil to be used; claim 1 mentioning 'a small proportion' . . . amounting to 'a fraction of 1% on the ore' and 12 'a fraction of 1% of oil on the ore.' Claim 9 mentions 'small quantity of oil.'

"On the question of infringement of the first patent I have no doubt. It was practically admitted by counsel for the defendant in opening the defense that it had infringed the three patents in suit by its operations at Miami within four months next before the filing of the bill. The defendant in its operations also used the minute proportion of oil mentioned in the first patent in suit. It does not use acid in its process, but this fact is immaterial so far as the question of infringement is concerned for the reason that it appears both from the claims and the description of that patent that the use of acid is optional. In the plaintiff's process the separation is effected through the rising of air bubbles to which are attached the metallic particles through the mixture to the top and the formation of a froth or scum on the surface, which can by simple means be removed with the contained metallic articles. In the defendant's process the separation is effected through the rising of air bubbles to which are attached the metallic particles through the mixture to the top and the floating away into a launder of either the original bubbles to which the metallic particles were first attached or succeeding and oncoming bubbles which have caught and buoyed up to the surface the metallic particles escaping from the bursting bubbles. The defendant contends that since its abandonment of its original infringing process at Miami it has not and does not infringe for the reason that it does not in its process produce the coherent and permanent froth of the process of the first patent. It appears from the evidence, it is true, that the bubble froth in the defendant's process is not as coherent and permanent as the froth of the process of the patent; but both are mineral froths and that of the defendant is sufficiently permanent to effect through air flotation an efficient separation of the metallic particles from the rest of the mixture. The defendant further insists that its process lacks violent agitation . . . but the description (of the patents) nowhere mentions 'violent agitation.'"

Regarding the third patent involved the court says: "I do not find any element of patentability in the process of this patent."

A decree was issued late last week by Judge Bradford staying an injunction obtained by Minerals Separation, Ltd., against the Miami Copper Co. pending appeal to the Circuit Court of Appeals, and the filing of a bond for \$250,000 by the Miami Copper Co. The former sought to enjoin the latter from continuing certain alleged infringement operations.

Leaching Copper.

At the Nevada-Douglas plant a somewhat new idea has been inaugurated in the way of hydrometallurgy. The original intention was to treat ores by the use of sulphuric acid as a leaching solvent, making the sulphuric acid from the gases obtained by roasting the sulphide. During experiments, however, it was found that the gases conducted directly from the furnaces into the leaching tanks proved to be a better solvent than sulphuric acid, besides saving time and expense. To manufacture sulphuric acid would cost from \$6 to \$12 per ton. Using the gases in place of the acid saves this expense. The gases are much more difficult to confine than the sulphuric acid solution and some trouble was at first encountered by leaking tanks, but the fault has now been remedied.

Drier for Finely Divided Materials.

It is claimed that paint materials, chemicals and the like are effectively and quickly dried in this revolving, cylindrical apparatus developed by W. V. Meyer, Chicago. It is in effect two cylinders, one within the other, mounted at a sharp incline so as to revolve on roller supports. A gas jet is directed through the interior of the inner cylinder, from the

REVOLVING CYLINDRICAL DRYING APPARATUS.

lower end, while the material to be dried is run in at the upper end and between the two cylinders. In between the cylinders are a large number of shelves having longitudinal ribs which retard the progress of the material on its passage through, and constantly lift it, throwing it upon the heated surface of the inner cylinder.

The litigation pending in the Utah courts between the Koering Cyaniding Process Co. of Detroit and the Wasatch Utah Mining Co. has been settled out of court. The mining company has settled, and in doing so has agreed to every demand made by the Koering people. This matter never should have been made a subject for litigation. The Koering Co. fulfilled every part of its agreement. On the other hand, the mining company, in order to cover up certain shortcomings, endeavored to repudiate its agreement. The whole trouble, it is claimed by the best of authorities, was that the mining company did not have sufficient ore for the plant to work on.

A 10,000-FT. METAL WATER FLUME IN COLORADO.

Remarkable Metal Flumes Built in the West

Some remarkable metal flumes are being built in sections at Denver, Col., at the Hardesty Sheet Metal Plant. One of these has a diameter of 8 ft. 4 ins. and a length of 2,400 ft., the average height of structure being 30 ft. It has concrete inlets and outlets and the approximate cost of structure was \$30,000, and was built for the Upperhanover Water Users' Association of Warland, Wyo. Some of the bents are 52 ft. in height.

A remarkable flume suspended on wooden truss was installed on the Greeley Poudre Canal at Greeley, Co., with a span of 70 ft. and a diameter of flume of 5 ft. Another metal flume on a steel structure was erected by the Twin Falls Canal Co. at Twin Falls, Ida. This flume is 14½ ft. in diameter and 300 ft. long.

A most interesting flume has been installed for U. S. Indian Service at Albuquerque, N. M. This is

a small flume, erected on steel, having concrete piers, which were cast in corrugated pipe. A great flume, 9 ft. in diameter and 10,000 ft. long, was installed in the Trincheria Irrigation District at Blanco, Col.

These flumes are used as short cuts across gulleys and low places, and are cheaper than detouring around the head of the draw, on grade with the canal, and have the advantage of shortening the canal, saving grade, eliminating seepage and preventing breaks. They are much cheaper and more durable than any kind of siphon construction, and have the additional advantage of being open, which prevents clogging with weeds, etc.

These flumes are semi-circular and have greater carrying capacity. In many places instead of the old, obsolete method of making an extensive and expensive earthen fill, with the canal at the top, liable to break at any moment, with seepage losses cutting down the

METAL WATER FLUME IN NEW MEXICO FOR U. S. INDIAN SERVICE.

supply of water, a metal flume is used to cross the low ground.

The drawing shows the details of construction of the Hess type of metallic flumes, also developed at Denver. In many instances the metallic flumes are attached to concrete head walls. It is only necessary to groove the concrete head wall section of a width and depth required to take the bed of the flume sheet, and set one anchor bolt at each end of groove and then fit cast shoes over these bolts under cross bar. When nuts are tightened down on cross bar, the shoes force the bevel bar collar into place, holding it securely and before attaching metal flume section to concrete it is necessary to fill the groove with fibre cement or oakum, then place flume section and register the bevel

SHOWING METAL FLUME UNDER CONSTRUCTION.

bar collar in the flume section groove. The shoes are placed over the ends of the bevel bar, the cross bar placed and then the nuts are tightened on the anchor bolts until bevel bar fits snugly in place.

This method gives absolutely water-tight joint, at the same time permits of adjustment should any part become loosened. Thus the first flume section becomes an expansion joint, and removes all danger of the flume being torn away from concrete through expansion and contraction. In cases where it is necessary to install both head walls before flume is assembled, the distance center to center of grooves in concrete must coincide very closely with exact length of flume; the groove in one head wall where last sheet is to be placed may be made 4 to 5 ins. in width to allow for any error of measurement. In such cases it is necessary to leave out anchor bolts and provide hole in concrete depth of anchor bolt and of diameter equal to width of groove. The last sheet is placed as above and then anchor bolts are adjusted to register with bead on outside of flume sheet and finally the anchor bolt is sealed with cement and after allowing the cement to set the above procedure follows.

These metal flumes are sometimes used as canal lining to prevent seepage and washouts. Metal lining will not crack or corrode under the action of alkali and is consequently more durable and dependable than concrete. Many miles of concrete canal linings have been replaced with flume lining, which in such cases has been used without any supporting structure. The flume is placed in the excavation,

with a slight back fill on the sides to prevent overturn. The only lumber required is for cross carriers to act as spreaders and complete the joint, or timbers may be run parallel with the edges of the flume, with an occasional spreader across the flume to prevent the earth from springing the lining at the top.

Preparing Waste Metal for the Smelter.

In order to make waste metals again fit for smelting, it is necessary to disintegrate them and separate from them any such coating as enamel with which they may have been covered. This has usually been done by passing the waste through rolls, in such a manner as to bend it, and also to pass it through intermeshing cutting disks which cut the metal into strips.

Both operations of removing enamel and disintegrating the metal, can now be performed by one machine, which literally crumples and tears the metal to pieces. This consists of two intermeshing trains of rolls with fluted surfaces, one above the other. A plan and end view are shown. Part of the rolls have their flutings extending lengthwise and part have

METHOD OF PREPARING WASTE METAL FOR SMELTING.

flutings at right angles. In passing between the two trains the metal is crumpled and torn in every direction and the enamel removed at the same time.

The machine has been patented by Alfred De Back of Essen-on-the Ruhr, Germany, and assigned to the Goldschmidt Melting Co. of New York.

Important sources of secondary lead are skimmings, drosses, old metal, and alloys, as babbitt, solder and type metal. The recovery of lead by refining these metals constitutes, according to the U. S. Geological Survey, an integral part of the lead industry. This business is mostly carried on at small refineries scattered over the United States, but the large smelters and refineries working primary lead frequently find it advantageous to incorporate material from secondary sources.

What the Mining Companies are Doing

Copper Production in September.

Following is a list of some of the larger copper producers, with figures of production for previous months and years:

MIAMI COPPER.

	1916.	1915.	1914.	1913.

Standard Silver-Lead, B. C.

The financial statement of the Standard Silver-Lead Mining Co. for the month of July shows as follows:

Receipts—	
Preliminary settlements for 129 tons of silver-lead ore and concentrates	\$ 47,775
Zinc sales, including back settlements	63,890
Impress	211
Boarding house	4,696
Total	\$116,572
Less final settlements for May and zinc penalties for February and March	17,028
Net receipts	\$ 99,544
Disbursements—	
Ore production, including mining, tramming, milling, shipping, marketing, power, general expense, salaries, taxes, etc.	\$ 28,521

Boarding house	3,607
Development	3,591
Construction	3,628
Axial tunnel	1,812
Store supplies	872
Home office expense	904

Total disbursements \$ 42,935

Cash statement—	
Net profit for July	\$ 56,609
Balance on hand July 1	289,772

Total \$346,381
Dividend No. 44. 50,000

Balance July 31. \$296,381

Recapitulation—	
Cash in banks	\$219,209
Ore shipped but not settled for	122,678

Total \$341,887
Vouchers payable and payroll. 45,506

Balance July 31. \$296,381

Shattuck-Arizona.

Following is the production figures given out by the Shattuck-Arizona Mining Co. for September, as compared with previous months:

	Copper lbs.	Lead, lbs.	Silver, ozs.	Gold, ozs.
September	1,566,446	233,800	26,928	419
August	1,699,575	253,343	30,542	568
July	1,327,445	171,091	22,525	314
June	1,446,080	61,889	24,636	367

Alaska United Gold Mining Co.

Returns for the month of August of the Alaska United Gold Mining Co. shows as follows:

	R. E. Claim, 700' claim.
Tons ore crushed	24,654
Tons concentrates saved	590.99
Estimated gross value of free gold	\$26,705.25
Estimated gross value of concentrate	27,026.50
Estimated total production	\$53,731.75
Estimated total realizable value	53,194.44
Operating expenses	33,254.17
Estimated operating profit	\$19,940.27
Construction expenses	7,925.18
Estimated net profit	\$12,015.09
Other income	3,730.00
Yield per ton of ore milled	2.18

Alaska Mexican.

The Alaska Mexican Gold Mining Co. reports for August as follows:

Tons ore crushed	15,959.01
Tons concentrate saved	346.53
Estimated gross value of free gold	\$15,959.01
Estimated gross value of concentrate	11,579.20
Estimated total production	\$27,538.21
Estimated realizable value	30,232.83
Operating expenses	16,461.08
Estimated operating profit	\$13,771.75
Construction expenses, etc.	4,606.09
Estimated net profit	\$ 9,165.66
Other income	3,730.36
Yield per ton of ore milled	2.32

*Loss.

Granby Con. Co., British Columbia.

Granby Con. produced in the fiscal year ended June 30, 12,198,083 lbs. of copper, 487,845 ozs. of silver and 41,848 ozs. gold from 1,897,251 tons of ore. Ore reserves were estimated at 23,156,000 tons, of which 9,947,000 tons average 2 to 2½% copper; 3,718,000 tons from 1 to 1½% copper, and 9,491,000 tons less than 1% copper. The Anyox smelter produced 29,-

562,177 lbs. of copper. Smelting and converting cost \$1,801 per ton.

The cost to the company for producing copper during the year was 12.3 cts. per pound, while interest and extraordinary charges raised the cost to 12.98 cts. The average cost at the Anyox smelter was 8.54 cts., against 10.09 cts. in the previous year.

The company's balance sheet shows as follows:

Assets—	
Mine	\$15,123,568
Real estate, etc.	5,212,748
Shares of other companies.	575,643
Materials and supplies.	1,041,012
Metals and ores.	2,782,868
Cash	144,448
Total	\$24,910,288
Liabilities—	
Capital stock	\$14,998,520
Bonds	3,042,306
Accounts payable	280,775
Liquidator dividends	1,222
Surplus	6,587,471
Total	\$24,910,288

For the first time in its history Granby did a gross business exceeding \$10,000,000. Of this \$9,299,337 came from the sale of its own copper, the balance being derived from custom ores treated.

A feature of the year's operations was the low recovery of copper from ore treated, the average being 22.36 lbs. per ton, against 23.99 lbs. in the preceding 12 months' period.

Production and recoveries from the various holdings are shown in the following:

	Tons ore.	1915-16	
		Lbs. recovered.	Lbs. copper.
Phoenix	1,097,299	14.6	15,992,476
Hidden Creek	722,630	33.23	24,012,838
Alaska mines	66,617	32.90	2,192,796
Total company's mines	*1,897,251	22.36	42,198,083
	Tons ore.	1914-15	
		Lbs. recovered.	Lbs. copper.
Phoenix	611,097	16.12	9,850,302
Hidden Creek	462,340	34.58	15,895,757
Total company's mines	1,073,437	23.99	25,746,059

*Including 10,705 tons from quartz mines which yielded an average of \$7.24 per ton in gold and silver.

J. P. Graves, one of the pioneers in Granby affairs and for years its general manager and one of the largest stockholders, has completely severed his connection with the company. Through the choice of Henry Bruere, former city chamberlain of New York, as his successor, the American Metal Co. representation on the board of directors was increased to two members.

Miscellaneous Company Notes.

The Rio Tinto Mining Co. has declared an interim dividend of 40s, compared with 35s 6 months ago, and 20s a year ago.

The Tonopah Extension results in August were as follows: Dry tons milled, 9217; ounces gold bullion produced, 1618.85; ounces silver bullion produced, 168,878; net profit, \$61,506.

John Hays Hammond and associates of New York have agreed to take controlling interest in a new corporation to take over Oro Belle Mines Co. at Hart, Cal., about 16 miles from Searchlight, Nevada county. Oro Belle has a shaft 850 ft. deep, with two veins.

Production and earnings of Goldfield Con. Mines Co for August shows as follows: Tons ore mined, 17,300; net, \$18,211. This compares with 26,700 tons mined in July, 29,000 tons in June and 32,400 tons in May. July net showed \$30,016; June, \$40,458, and May, \$52,500.

Judge Manton filed an order last week in clerk's office of U. S. District Court at New York allowing International and Intercontinental Mining & Refining Corporation, as holder of 9000 shares of capital stock of Ohio Copper Mining Co., to intervene in the foreclosure proceedings against Ohio Copper Co. Corporation seeks to have the order for the sale set aside and to prevent the levying of an assessment of \$2

a share on the stock which is proposed by the reorganization committee.

The Champion Copper Co., according to present estimates, is earning close to \$7,000,000 annually. A \$6.40 per share monthly dividend has been declared for several months past. A half interest in Champion is owned by the Copper Range Co.; the dividends which it receives from the former practically takes care of its own dividend requirements.

With the consent of all parties Judge De Courcy of the Supreme Court at Boston dismissed the cross bill between the Old Dominion Copper Mining & Smelting Co. and the New England Trust Co. This suit had reference to funds recovered from A. S. Bigelow which were some time since distributed to holders of Old Dominion "trust receipts."

The Anaconda Copper Co. is reported producing at the rate of 340,000,000 lbs. of copper a year. With metal selling at 25 cts. a pound, the company would earn at the rate of \$23 a share. It is expected that in the current calendar year and in 1917 the profits will make a grand total of \$100,000,000. There is some reason for this expectation, since copper for delivery in the first half of 1917 is now selling at 27 cts. a pound.

It is understood that new interests will enter the management of the Tennessee Copper Co. According to the report stockholders will be offered the right to subscribe to new stock at about \$16 a share, on the basis of one new for each share now held. The company owes about \$2,000,000, including floating debt, of which approximately \$1,000,000 constitutes a liability due the Russian government. Additional funds will be raised by the proposed plan to give the company sufficient working capital. The status of the convertible bonds remains unchanged, holders of these securities will not be offered subscription privileges.

Utah Metal & Tunnel Co. is showing steady improvement. The present excellent financial situation was the result of discovering two rich ore bodies which soon added \$1,000,000 to the treasury. At the present time the company is earning better than \$1 per share on its 685,000 shares, and this after charging from \$20,000 to \$25,000 per month for development and an additional \$5000 for a flotation plant which is in process of installation. Financially the company is in good condition, with about \$500,000 in cash in the bank, besides \$175,000 due for metals sold but not yet delivered. The company has recently purchased \$125,000 of its bonds, leaving \$235,000 outstanding.

Inspiration will produce approximately 125,000,000 lbs. of copper this year and continued operations in 1917 should result in a production of 150,000,000 lbs. Net earnings for this year are placed at around \$22,000,000. Total recovery from all ores has gradually improved to about 80%, while an average yield of about 83% is anticipated. The recovery from sulphide ores alone has been not less than 90% and more often 93%. An average cost of production of less than 8½ cts. a pound is expected to be shown in report for the year 1916. Further mill improvements will lower this item. Exclusive of eastern expense, Inspiration has already produced copper for less than 8 cts. a pound.

The International Nickel Co. has set aside \$5,500,000 from cash on hand for construction of a refinery in Canada and extension of its smelters and other facilities. All this money will be spent in Canada. It has been realized by directors that present capacity of its plants is inadequate to meet demands for nickel. Consequently enlargement and new construction program will be begun immediately and will be rushed. This expenditure will eventually be capitalized and distributed to common shareholders in a stock dividend, following custom of the Nickel management. Capitalization of this investment would indicate that the stock dividend when authorized will amount to 10% or higher. Last previous distribution in stock was 10%, last year. On the basis of dividends of 24%, or \$6 a share, International Nickel, at present figures, yields better than 12% on the investment. It has been the history of the company that dividends are on a steadily rising scale despite the fact of stock distribution in the interim.

**Copper Prosperity and Copper Share
 Prices.**

In volume of business closed the month of September has established a record in the history of the copper trade. Orders for a total of 600,000,000 lbs. of copper were written into the books of copper producers. What this enormous total means is readily conceivable when it is contrasted with the present monthly refinery yield of 165,000,000 lbs. or with the prospect that the production of copper in the first half of next year will amount to approximately 1,000,000,000 lbs.

Out of the total of 600,000,000 lbs. it is reliably figured that 500,000,000 lbs. are for delivery in the first half of next year. This means that September business alone furnished orders for one-half of the output of the first six months of next year. Adding the business taken in August on which delivery is to be made in the first half of 1917 and it is readily apparent that as October opens the producers have disposed of 70 per cent or 700,000,000 lbs. of the 1,000,000,000 lbs. they hope to produce between January and June of next year.

With business still coming in at a rapid pace it is more than likely that on November 1 the producers will have firm orders in hand for 80 and possibly 90 per cent of the entire first half output. This is an achievement without parallel in the industry. These figures are *sufficient* to furnish a support for high prices.

Despite the fact that the copper properties are fairly reveling in prosperity, stocks are not selling at their fair worth, as shown in the table herewith. Properties are earning an unusually high rate at present with copper figured at 27 cts. a pound. But one company is earning less than 20% on the selling price of its stock as of Oct. 2, while one company is returning close to 40%. Anaconda, the largest producer, is yielding at the rate of 22% on the selling price of its shares, while Utah Copper returns 28%. Granby really makes the best showing, earning no less than 35% on its present share price of 92 1/8. Calumet & Hecla, with its share price at \$580, is earning at the rate of 22%, while Kennecott, at \$55.75 per share, is earning at the rate of 24%. Inspiration, with its stock selling at 67 3/8, returns to holders of the stock no less than 26%. Wolverine, with its stock at 49, yields earnings of 40%.

The average earning power of the 23 companies mentioned below, with copper at 27 cts. per pound and stock selling as of Oct. 2, is 27%. According to reports made to Mining and Engineering World, the 23 companies disbursed no less than \$79,077,247 during the 9 months of the present year. A wonderful demonstration of the earning powers of American copper properties.

In the following table is given the earnings of 23 of the leading copper producers, with the selling price

of copper at 27 cts. per pound and the per cent return on the selling price of stock as on Oct. 2:

	Earnings on 27- ct. copper per share.	Stock selling Oct. 2.	Per cent earnings on price of stock.	Dividends 9 mos. to Oct. 2.
Ahmeek	\$20.00	\$106.00	19	\$ 1,200,000
Allouez	16.00	69.50	20	450,000
Anaconda	22.00	96.37½	22	11,656,250
Calumet & Arizona.....	19.50	76.00	25	3,849,522
Calumet & Hecla.....	126.50	580.00	22	5,000,000
Chino	15.50	56.50	27	5,002,385
Copper Range	16.50	70.50	23	2,381,305
Granby	33.00	92.12½	35	749,926

Wolverine	13.75	49.00	40	360,000
Average	\$22.35	\$ 90.98	27	*\$79,077,247

*Total dividends for the nine months of 1916.

Anent Dividend Statistics Published in These Columns.

Mining and Engineering World feels greatly encouraged in its work in giving to the world dependable statistics of the dividend payments of American mines and works, when such a representative paper as the *Denver Post*, through its mining editor, General Frank Hall, comments on same thus favorably:

We are presenting these compilations as they appear from month to month in Mining and Engineering World in order that the people may see what the mining industry is doing in the way of taking wealth from the mines and scattering it among the people. It is a great lesson to be studied by everybody who feels the impulse given to our country from one source of endeavor.

When we consider that the monthly dividend summary as published in these columns is republished regularly in from three to four hundred papers and magazines in this and foreign countries, and the favorable publicity given American mining thereby, we feel amply repaid for the very large amount of labor this work entails.

We also appreciate the honesty and fair-mindedness of a very large majority of publishers in properly crediting the source of these reports. As to others, we trust that the credit they receive for their enterprise (?) in presenting these figures to their readers as their own compilation will be, to a degree at least, sufficient to offset any twinges of conscience which may (?) arise from their discreditable pilfering.

Rescue and Recovery Operations in Mines After Fire and Explosions.

A work deserving much praise is that now being conducted by the U. S. Bureau of Mines, having for its object the education of miners in rescue and recovery operations after fires and explosions. The work is being conducted in all the mining centers of the country by means of public lectures illustrated with

lantern slides and moving pictures. First aid to the injured is taught by training miners in the use of rescue breathing apparatus and by lectures on rescue and recovery methods. All this instruction is furnished without cost to the miner.

It is the aim of the Bureau to extend this educational work, to train a large number of miners in the use of rescue breathing apparatus, to induce operators to establish rescue stations provided with breathing apparatus, and to keep crews of men trained to use the apparatus immediately when life may be saved.

A pamphlet, in handbook form, entitled, "Rescue and Recovery Operations in Mines After Fires and Explosions," by James W. Paul and H. M. Wolfelin, has been issued by the Bureau, which should be in the hands of every mine operator and superintendent in the country. It covers both coal and metal mines and has for its object the development of an organization at disasters, to show what materials ought to be on hand and how the authority should be placed. The pamphlet is the result of serious studies covering a period of considerable time on what the Bureau believes to be the best method in rescue and recovery operations in both coal and metal mines after fires and explosions. It outlines a method of procedure for the operators and miners to follow in such emergencies and explains just what part the Bureau of Mines is expected to take in such work.

Under terms of agreement entered into last year between the Anaconda Copper Mining Co. and the Inspiration Con. Copper Co. on the one hand and the Minerals Separation, Ltd., on the other, the two mining companies must be paying royalties of 4 cts. per ton on their ores handled by flotation. This appears plain from a reading of the agreement which was entered into in February, 1915. Prior to that time the Inspiration Co. had a license agreement with the Minerals Separation, Ltd., under date of April 10, 1913. The subsequent agreement, however, included the Anaconda Co., and if desired the Greene-Cananea Copper Co., Arizona Copper Co., Calumet and Arizona Mining Co., and Consolidated Copper Mines Co.

As a result of the steamship service started by the American Smelting & Refining Co., a cargo of approximately 5000 tons of copper was received last week by that company from Chile. These steamers will ply between South American ports and the United States and will handle the product from the Guggenheim properties in South America—Braden and Chile Copper companies. Braden formerly shipped practically all its blister copper to Europe, where it sold on the basis of "standard" prices on the London Metal Exchange.

The payroll of mining companies in the Lake Superior copper district is now close to \$2,500,000 monthly, the largest on record. Never was there a time in the history of the district when there was so many men at work, when the pay per man was anywhere near as large as at present, when industrial conditions were as prosperous as at present.

PERSONAL.

D. C. Jackling is inspecting the Butte & Superior property at Butte this week.

S. S. Pond recently inspected the property of the Yankee Con. Co. at Tintie, Utah.

J. V. Richards of Salt Lake, Utah, is making an examination at Yomocalla, Ore.

A. B. Shepherd of Pittsburgh, Pa., was in the Lake Superior iron country last week.

F. E. Marcy, consulting engineer, has opened offices in the Atlas building, Salt Lake City.

John G. Kirchen recently examined the holdings of the White Caps Mining Co. at Mahattan, Nev.

H. I. Wilson of Butte, Mont., recently inspected the Granite-Poorman mine, near Nelson, B. C.

F. E. Marcy, inventor of the Marcy ball mill, has established offices in the Atlas block, Salt Lake City.

A. G. Burritt of Salt Lake City, Utah, recently completed an examination trip through southern and eastern Idaho.

J. S. Schuyler, who recently inspected copper properties in British Columbia, will leave New York shortly for Chile.

R. E. Mace of Duluth, Minn., purchasing agent for the Oliver Iron Mining Co., was in Ishpeming, Mich., last week.

F. A. Knapp of Portland, Ore., has completed an inspection of the Portoma property in the Coeur d'Alene region, Idaho.

George A. Bethune of Kingman, Ariz., will make an inspection of the property of the Chloride Central Mines Co. at Chloride, Ariz.

Charles E. Van Barneveld, formerly chief of the department of mines at the Panama-Pacific exposition, was in Salt Lake City last week.

W. Earl Greenough has resigned as managing director of the Marsh Con. Mining Co., operating in the Coeur d'Alene district, Idaho.

W. F. Downs, chemical engineer, and Kirby Thomas, mining engineer, New York, are making an investigation of peat deposits in New Jersey.

H. J. Stander, flotation engineer, recently returned from a visit to Alaska and British Columbia. He will visit Denver, then to Arizona and later to Ontario.

H. L. Christensen has been appointed mill superintendent for the Alaska-Juneau Gold Mining Co. He formerly held a similar position with the Miami Copper Co.

E. P. Mathewson, general manager of the Washoe smelter of the Anaconda Copper Mining Co., has resigned to become general manager of the British-American Nickel corporation.

L. S. Ropes, mining engineer of Helena, Mont., who has been looking after the development of several groups of claims at Marysville, has been appointed consulting engineer for the Marysville Gold Mining Co.

J. G. Rutherford, formerly manager of the Motherlode Mine in the Sheep Creek district, British Columbia, and more recently in charge of the Molly group in the same camp, has accepted a position in the Cobalt camp, Ontario.

Edwin Higgins, chief mine inspector for the Industrial Accident Commission of California, has accepted the position of consulting and safety engineer for the California Metal Producers' Association. He will assume his new duties Nov. 1.

OBITUARY.

H. F. Robertson, for 2 years manager of the Empire Copper Mining & Milling Co. in the Little North Fork district, Idaho, one of the best known and experienced mining engineers in the Coeur d'Alenes, died recently from pneumonia. Mr. Robertson was about 43 years old. He was a graduate of the Massachusetts Institute of Technology.

Adolph J. Zang died in Denver, Colo., Sept. 28. He had long been identified with successful mining enterprises of the west, among which were the Vindicator Con., the Cresson Con. and the Rare Metals Ore Co. Deceased was 60 years of age and had lived in Denver about 35 years.

SCHOOLS AND SOCIETIES.

Canadian Mining Institute; Western Branch.—The special meeting of the western branch of the Canadian Mining Institute will be held in Trail Oct. 26, according to announcement from E. Jacobs, the secretary.

American Iron and Steel Institute.—The general meeting of the American Iron and Steel Institute, to be held in St. Louis Oct. 27 and 28, will open with an address by the president, Elbert H. Gary. Other speakers will be Clarence H. Howard, Dr. G. B. Waterhouse, James W. Fuller, Frank S. Witherbee and Arthur J. Boynton.

NEW PUBLICATIONS.

Triangulation and Primary Traverse in Washington, 1913-1915. By R. B. Marshall. Washington, D. C., U. S. Geological Survey. Bulletin 644-Q; pp. 10.

Description is given for the location of triangulation stations in the state and this is followed by tabulated data for survey work and computation, such as azimuth, back azimuth and distance.

Mining Developments and Water-Power Investigations in Southeastern Alaska. By Theodore Chapin and George H. Canfield. Washington, D. C., U. S. Geological Survey. Bulletin 642-B; pp. 55; illustrated.

A considerable advance in both copper and gold lode mining was noted in southeastern Alaska in 1915. The development consisted in the opening of large bodies of ore, in the installation of machinery and power developing plants and in the resumption of operations at a number of mines. It is these operations and the general revival which make up the text for this report.

Health Conservation at Steel Mills. By J. A. Watkins. Washington, D. C., U. S. Bureau of Mines. Technical Paper 102; pp. 36.

Though the title of this paper would infer that it is of little interest to the mining profession, this will be found an illusion. Things which tend to make a man less efficient in his work in the steel mill will be found equally as applicable to mines and plants about the mine. For example "fatigue as a cause of disability" and "noise as a cause of lowered efficiency" are dealt with as are other topics of a similar nature.

Economic Geology. By Heinrich Ries. John Wiley & Sons, Inc., New York. Book; pp. 856; illustrated. For sale by Mining World Co., \$4.

This is the fourth edition of this book and has been revised and brought as nearly up to date as possible. It is stated in the preface that statistics have been largely obtained from the U. S. Geological Survey and Canadian Department of Mines. The results of investigations which were too late to include in the text have been placed in the refer-

ence list. The book is divided into two parts, one treating on non-metallic minerals and the other on metallic deposits. The information given on each separate mineral is similar to that given in other texts on "economic geology," namely, the nature of the product, location and general mode of occurrence, some description of the districts in which the product is found, genesis and geology of deposits in general and some statistics on production.

Mineral Resources of the Upper Chitina Valley, Alaska. By Fred H. Moffit. Washington, D. C., U. S. Geological Survey. Bulletin 642-C; pp. 8; illustrated.

This area is located in the upper part of the well-known Copper River basin. Both geology and geography of the country are embodied in the bulletin. In reviewing the mineral resources it is brought out that both gold and copper have been found in the district, though neither has been produced as yet in paying quantities.

Elements of Mining. By George J. Young. McGraw-Hill Book Co., New York. Book; pp. 628; illustrated. For sale by Mining World Co., \$5.

The text is concise and of a more elementary nature, being of particular value to those who desire a general rather than detailed knowledge of mining and the data affiliated with it. The different subheads under mining are treated on separately. Specific data and descriptions are given and the different subjects are treated in a complete manner. Prospecting and drilling; drilling and blasting; transportation; drainage; ventilation; supports; open-pit and placer mining; development; underground methods; mine organization, operation and accounting; accidents and diseases and examination of mines and deposits are all dealt with.

TRADE PUBLICATIONS.

Flooring for Plants. Ayer & Lord Tie Co., Chicago. Booklet; pp. 15; illustrated.

On every other page of the booklet views are shown of plants with floors made of A. & L. interior wood block flooring. In a concise manner the descriptive contents of the booklet brings out the features of this kind of flooring and gives a general review of its nature. Among some of the features it is noted that this type of flooring does not tire workmen so as to reduce their efficiency so quickly as other classes of flooring.

Fuel Oil Appliances. W. S. Rockwell Co., New York. Bulletin No. 31; pp. 27; illustrated.

There is an insert showing the plan in general for an oil burning plant and this includes the handling of the oil from the tank car to the storage tank and then through the pump and blower to the furnace. Among the headings noted in the bulletin are the following: A Word About Oil Burners; Rockwell Oil and Gas Burners; Burner Plates; Fuel Oil Pumps and Systems; and miscellaneous other descriptions of equipment used in connection with this method of firing.

Fans for Mechanical Ventilation, Etc. Clarage Fan Co., Kalamazoo, Mich. Catalog No. 5; pp. 24; illustrated.

The fans are of the multi-blade wheel type and it is stated in the contents of the catalog that they show high efficiency and that those carried in stock will work against a head of 5 ins. The fans are briefly illustrated and described and 10 pages are given to the reproduction of capacity tables. A separate table is given for each class of fan and the tables include volume, outlet velocity, static pressure, R.P.M. and B.H.P. A dimension table is also given with a lettered dimension drawing.

The Caterpillar Tractor. The Holt Manufacturing Co., Peoria, Ill. Booklets; pp. 31; illustrated.

In the booklet, "Hauling with a Holt Caterpillar," a comparison is made between haulage with caterpillars and horses. Following this is general talk and information regarding the machine, its uses and advantages. Illustrations are given of the tractor in practical use, and among some

of its advantages it is brought out that the machine will haul over any kind of roads. It is also shown by illustration and description how the machine in traveling resembles a railroad engine, which lays its track as it goes and picks up the track from behind as it travels to make the track for travel ahead. The other booklet contains information of a similar nature, but in addition there are drawings and descriptions bringing out the construction of the machine in a more complete way.

Large Piping Material and Fittings. The M. W. Kellogg Co., New York. Catalog; pp. 87; illustrated.

The first 33 pages of the catalog are confined to listing the company's product. Separate tables are given for different kinds of pipe, all of which are suitable for different purposes. Ordinarily a drawing with dimension lines lettered is given with each table and prices are included. The pipe herein considered is of welded steel with flanged joints, and it is announced that the company handles the complete design of piping systems on request. The concluding 54 pages is in general a text on up-to-date piping practice. Curves, tables, illustrations of installations, description and specific information of use in designing pipe work, mostly for steam plants, is dealt with.

INDUSTRIAL AND TRADE NOTES.

The Weigle Pipe Works, Denver, lately shipped 4000 ft. of 12, 10 and 8-in. riveted pipe, for placer mining operations, to P. A. Danaher, Helena, Mont.

Morse Brothers' Machinery & Supply Co., Denver, has purchased the equipment of the Cook Railway Signal Co., that city, consisting of motors, generators, batteries, laboratory and office equipment.

The Arizona-Hercules Copper Co., Ray, Ariz., lately gave the Mine & Smelter Supply Co. an order for three No. 86 Marcy ball mills, for installation in the former company's copper concentrating mill, being constructed after designs by Geo. O. Bradley, San Francisco. These ball mills weigh 50 tons each.

Denver Quartz Mill & Crusher Co., Colorado building, Denver, has received an order from Talkeetna Mining Co., Seattle, for one mill and feeder of that type, for installation at the latter company's mine at Knik, Alaska. This is the third mill of Denver Quartz Mill make which has been shipped to that part of Alaska. The order was transmitted by wire.

Plains Iron Works, Denver, Colo., recently built and shipped machinery for a sizing and screening plant for the Indian Creek Coal Co., Junction City, Colo. Another order just filled was for 20 heavy ore cars for the Hanover Bessemer Iron & Copper Co., near Santa Rita, N. M. Steel hoppers were built in these shops for the new sampler of the Portland Gold Mining Co., Victor, Colo., and about 50 centrifugal sand pumps are being made on orders from the Traylor Engineering Works, for pumping mill tailings and pulp. A large number of sheaves are being made for mine hoists.

While the other two members of the electrical "Big Three" have been enjoying record prosperity, Western Electric has not been sitting idly by. The company's previous biggest year's gross was \$77,000,000. This year sales will be not far from \$100,000,000. This refers to actual shipment of goods to customers. The incoming orders booked will be very much greater than \$100,000,000. While Western Electric has no war orders, it has felt the effect of the war by limitation of raw material supplies on the one hand and an abnormal demand for its products on the other. Directors recognize the fact that present conditions are entirely abnormal. At the same time the pressure is here and cannot be entirely ignored. As a result directors have authorized plant additions which will call for the expenditure of over \$1,000,000. Western Electric is now employing 23,000 people, the largest number in its entire career.

Late News From the World's Mining Camps

Editorial and Special Correspondence.

ALASKA.

Valdez.

Nick Meckem and H. E. Hills are operating ground near the Teikhell roadhouse. They have recently taken good specimens from the property which run fabulously high.

Seward.

According to W. E. Edes, chairman of the Alaskan Engineering Commission, the first train will run from this city to Fairbanks in 1919. At present a little coal is being purchased by the Commission from Dick Doherty. He is working on the edge of the coal fields. The first coal hauled over the railroad was taken from there to Anchorage recently. In the near future, or before the end of the season, the railroad will be into the heart of the coal fields. In regard to progress this year from Matanuska Junction, toward Fairbanks, Mr. Edes says that it is probable that steel will be laid for a distance of 15 miles from the point where the road cuts off to the coal fields. Continuing, toward Broad Pass, there will be quite a big stretch of the line that will be cleared and graded, ready for the laying of the rails next spring.

ARIZONA.

Jerome.

The mine workings of the Jerome Victor Extension Copper Co. have been freed of water and the work of development is being pushed with three shifts. To avoid water troubles in the future, the big pump on the 700 level is to be lessened by the installing of a 250-h.p. electric pump. There is no question but the two pumps will adequately handle the present and any future flow that may be tapped. The directors, several of whom are actively identified with the large copper mine of the Lake Superior country, are lending financial and advisory support to the Victor Extension management and will supply additional machinery equipment as it is needed. The company has about \$125,000 in its treasury, accumulated from the sale of its stock at from \$1 to \$3 per share, and has placed its property in charge of George W. Salisbury, who for a number of years was a member of the engineering staff of the United Verde mine adjoining. Drifting is now going on on the 1200 level with the object of tapping the continuation of the United Verde ore bodies. No. 3 United Verde shaft has a depth of 1950 ft., and it is stated that the laterals on the 1650 and 1800 levels have been driven well toward the Victor Extension lines. It is also stated that the United Verde Co. will sink its new shaft—to be known as No. 6—to the east of the railroad depot at Jerome, and in the vicinity of the Victor Extension's boundary. It is to be a 3-compartment, and through its medium a large area of great prospective value will be developed. Operations on the 1200 level in Victor Extension workings will demonstrate the value of this area beyond the United Verde's lines. The drift on the 1200 level is out from the shaft 175 ft. and will be extended 75 ft. further. There a crosscut will be run about 30 ft. to tap, on its dip, the downward extension of the deposit exposed on the 700 level. The vein matter on the 700 level, although leached and considerably shattered, shows mineralization across a width of 30 ft.

Prescott.

For about a year the Verde River Copper Co., a corporation headed by Arthur L. Garford, of Ohio, has been developing the old Pfau group. A crosscut tunnel, recently com-

pleted, has been driven a length of 600 ft., and has intersected a number of ledges carrying very encouraging copper values. Near the face of the tunnel a ledge has been cross-cut that carries pay values in gold. Garford and his engineer will arrive at the property some time this month for the purpose of making an examination and deciding upon further development plans.

The Commercial mine in Copper Basin is shipping from 80 to 100 tons of copper ore daily, and the Loma Prieta mine, adjoining the Commercial, shows a strong body of copper ore.

A deal is practically closed for the transfer of the Alvarado group to a party of New York mining and business men. The property is located in the Congress country, and in past years was noted as a producer of high-grade silver-gold ore. To a depth of 500 ft. the ore offered no reduction problem which could not be solved by the reduction processes of 20 years ago. Below that depth, however, it became so base that mining at a profit became impossible and work ceased. It is now planned to open the ore bodies at greater depth and to establish an up-to-date mill for their reduction.

Globe.

E. R. Rice, for 4 years efficiency engineer for the Copper Queen and who drilled the Miami Southwestern for Payne-Weber interests, has been engaged to superintend drilling operations at the Inspiration Needles Copper Co.'s property.

Favorable development at the Old Dominion property has been the discovery of high-grade oxidized ore on the 16th level west, running from 8 to 10% copper. Old Dominion has had this oxidized ore body from the 9th level down, but the fact that it is of such high grade on the 16th is, of course, very significant. Incidentally, the strike should help Arizona Commercial, as any increase in shipments of oxidized ore from old Dominion will permit of treatment of larger tonnages of Arizona Commercial's sulphides at the Old Dominion smelter. Old Dominion continues to produce from 31,000,000 to 32,000,000 lbs. of copper per annum at a cost of less than 10 cts. Its smelter output has been running much in excess of this, but a very considerable tonnage of ore has been coming from United Verde Extension and Arizona Commercial.

Miami.

Profits approximating 5,670,000 will have accrued to Miami Copper Co. from operations during the first 9 months of this year—estimating September. This will be equal to \$7 per share, or more than sufficient to meet a full year's dividend requirements at the current \$6 rate. Surplus amounts to about \$5,000,000, which will have been augmented materially by the time the November payment of \$1.50 per share falls due. Profits for the six months ended June 30 totaled \$3,199,000. It is estimated that profits for the third quarter will approximate \$2,150,000, or 66 per cent of the net for the first six months. Miami has sold itself well ahead at high prices. Although not participating in the big copper sale, Miami has effected sales through the early months of 1911 at prices equalling and in some instances higher than the average to be paid on the big export contract.

Hayden.

Referring to Ray Hercules, a conservative estimate places the tonnage at upward of 10,000,000, on an average of 2½% or better in the Ray Hercules. Considerable native copper has been encountered in the shaft at a depth of approximately 675 ft. and sinking is progressing rapidly at the rate of about 5 ft. per day. Three churn drills are working. The directors do not give out any official figures, but have ordered equipment for a 2000-ton mill instead of 1000 as originally intended, and expect to be producing copper within a year.

The property end is looking fine and the directors are not inclined to pay any attention to the stock market end.

Phoenix.

A 16-h.p. Western engine hoist, mining cars, buckets and 350 ft. of cable have been unloaded at Wenden and were taken to the property of the Wenden Copper Co. this week. Twenty thousand feet of lumber have been delivered to the mine and work of erecting the head frame will begin soon. The first 50 ft. of the shaft will be completed by hand drilling, it is announced.

Oatman.

At a called meeting this week the stockholders ratified the recent sale of control of the Sunnyside mining property to those who control the United Eastern. By the terms of the deal the treasury is enriched to the extent of \$86,500 in cash and work will proceed on the same plan that made the Eastern mines. The purchasers are Sceley W. Mudd, Colonel D. C. Jackling, F. A. Keith, Philip Wiseman and C. H. Palmer Jr. The former management was composed of S. S. Jones, P. L. Mullen, W. H. Flanigan and L. C. Monks.

CALIFORNIA.

Grass Valley.

Connecticut capitalists, headed by Frank L. Rodgers, are interested in a syndicate which has taken under bond and option the Prudential and Norambagua gold properties. Both properties have produced rich ore and the Prudential has been opened to an approximate depth of 1000 ft. It is planned to extend drifts into the Norambagua from the Prudential shaft and operate the mines from a central point. The Prudential is equipped with a small mill and mine machinery.

Redding.

The Potosi mine at Muletown, 6 miles west of Redding, has been taken under bond by a company and work started, with A. S. Howe, superintendent. The mine has lain idle 45 years, although for a short time it produced some rich gold ore. It belongs to the estate of the late Senator Jones of Nevada.

The Mammoth Copper Co. has completed the tramline from its Stowell mine to the main haulage system, and the ore is going direct to the smelter. Construction of the \$350,000 electrolytic zinc plant near Kennett is proceeding. It is reported the plant will handle custom ore in addition to the product from the bag house and the Mammoth line. A small commercial unit embodying the process has been operated for several months at Winthrop by the Bully Hill Copper Co., and it is reported this corporation is perfecting arrangements for the building of a large plant next summer.

Oroville.

Arrangements have been made to operate the plant at the Banner group with electric power. Late developments in the property have been highly satisfactory, particularly in the South Banner. All the quartz is of good milling grade. Richard Phillips is manager.

Karl Brehme and associates of Los Angeles have applied to the Debris Commission for a permit to work placer ground near St. Louis by the hydraulic method. The new dam across Slate creek is rapidly nearing completion and will cost in the neighborhood of \$40,000. It is 30 ft. high and constructed throughout of reinforced concrete. Several companies in the district have applied for permission to hydraulic their holdings, and an abundance of water has been assured for the numerous projects.

Greenville.

The Southern Eureka Co. has arranged for resumption of work at the Southern Eureka and Wardlow mines. Rich quartz has been opened in both mines and as soon as sufficient profitable quartz is exposed arrangements will be made for installation of reduction facilities.

The Boyden and McMillan copper-gold claims have been acquired by Salt Lake capitalists and arrangements made for extensive work. The Ruby copper-gold mine is being worked

under the management of Lester Williams. Several other properties are receiving attention, due to the building of the Indian Valley railway through the district.

Jackson.

The strike situation continues unchanged. Little violence has developed and the companies continue to keep pumps active and repairs are going forward. The Miners' Union has issued a statement to the effect that recognition of the union will be waived provided the increased wage scale of 25 cts. daily is paid. As the union question was not mentioned in the original demand, operators have ignored the latest attitude of the men.

Placerville.

The Frog Pond quartz mine in the Garden Valley district has been taken over by N. H. Burger and associates of Placerville. The mine has produced much rich ore and is considered one of the best propositions in this section of the Mother Lode territory. The shaft will be deepened and extensive lateral developments prosecuted.

Sutter Creek.

Unwatering of the shaft at the Old Eureka continues to be steadily conducted, despite the strike and bad caves below the 600. The sawmill has been finished and construction of surface buildings is proceeding. The new hoist will soon be in position and the management is hopeful of starting active mine operations early in January.

At the Central Eureka everything is being placed in shape for resumption of shaft sinking as soon as the strike ends. It is planned to sink to a depth of 3400 ft. and crosscut to reach two veins believed to parallel the main ledge. Repairs to the shaft are being made with a small crew.

Porterville.

An improved demand for magnesite ores has stimulated developments in this vicinity and contracts have been signed for the delivery of 100 carloads of crude ore within 30 days. This is in addition to the regular output. The American Magnesite Co. and Tulare Mining Co. are arranging to augment the capacity of their calcining plants. This will increase the local output to 2 cars of calcined ore daily.

Goldstone.

Vigorous developments are proceeding at the Goodrick silver mine. The shaft is down 147 ft. and the ledge is 4 ft. wide with values running into high figures. Silver predominates, but there is a little gold and copper.

The gold mining companies are increasing activities. The United Goldstone Co. has started work on the Shamrock claim, where a good ledge is exposed near surface. Three claims have been leased to Ramsey & Schwartz of Santa Monica. Alexander & Hale have acquired the Goldstone Townsite group and started work. The custom mill is running and is reported to be making a good extraction. Motor trucks are delivering ore from numerous leases.

Callahan.

The McKean ledge has been struck in the upper tunnel of the McKean mine and is showing well with development. No. 2 tunnel is advancing rapidly and a raise has been driven to connect with No. 1 tunnel workings. Good ore is coming from both points. Plans have been made to equip the mill with heavier machinery. Twenty men are employed. W. L. Fraser is superintendent.

A deposit of chrome ore has been discovered near this point by H. A. Eaton, W. H. Gassoway, Alex. Parker and M. F. Barnum. The ore is of excellent grade and a road is being constructed to facilitate early shipments. Gold prospecting is very active in this section and some promising discoveries have been reported. Several companies are preparing for placer work.

Campo Seco.

In December, 1914, 31 ranchers in Jackson and Calaveras counties entered suit against Penn Mining Co., a copper smelter, for damage alleged to have resulted from smelter fumes to vegetation and stock. Ten of the cases were tried in May, in the U. S. District court at San Francisco; verdict was given defendant, at plaintiffs' cost. The remaining 21 cases have been dismissed without trial, and without payment of any damages.

COLORADO.

Cripple Creek.

The Dante mine is under lease to the Consolidated Gold Mines & Reduction Co. and Frank Cottier is in charge. He is arranging for the installation of an electric hoist. A 35-hp. hoist will be installed and an electric compressor will also be purchased. The lease covers a 5-year term.

An ore shoot has been opened by the Cripple Creek Deep Leasing Co. prospecting the granite-schist contact lying east of the shaft by drift from the 750 level. It has ore of \$20 to \$30 value. Assays showing a much higher gold content are of common occurrence, but the value as given is the shipping grade of the ore as mined.

The electric hoist at the Little Daisy has been taken to the Big Banta property, which is owned by the United Gold Mines Co., and has been secured under lease by the J. H. B. Leasing Co. Matt Edwards, Victor, superintendent for the company, has a force of men engaged laying an air line from the Ajax shaft. A new shaft house has been constructed and new headframe erected. Development work will commence as soon as the hoist is in place and connected with the power line. A trial shipment of low-grade ore shipped from the lease gave satisfactory results.

The Black Diamond claim of the Portland Gold Mining Co. has made its initial shipment under the leasing operations of F. Bishop and associates. The lessees have constructed a temporary ore bin. About 30 tons of ore was on the plat. They are sinking a new shaft on this block and everything taken out from grassroots down to the present depth of about 35 ft. has been ore. The Black Diamond cuts across both the Strong and W. C. Dillon, the last named owned by the Granite Gold Mining Co. and north of the Bishop discovery and higher up on the mountain, H. P. Jones and associates have also opened up ore on the same vein and have loaded out their trial shipment. Jones and partners are sinking a new shaft for the Granite Co. on their block of the Dillon claim.

A new electric hoist has been installed at the Last Dollar. The mine has been secured under a 5-year lease by Charles Walden, Victor. Active operations underground have been started.

Leadville.

On Sept. 29 the Mikado shaft, being retimbered by Contractor J. Nilson, was completed to within 40 ft. of the 900 or water level and the remainder was expected to be finished in a week or so. A new engine room 30 by 36 ft. and a compressor room 18 by 36 ft. are under construction. New machinery has been ordered for the property. The Denver & Rio Grande Railway Co. has started the work of grading for a switch which is to be put into the Mikado from the Greenback property, about 600 ft. away. This will be completed early enough to handle the heavy shipments of machinery that are to be delivered, including pumps, compressor and hoist.

The Lanyon Zinc Co. is now sinking a new shaft on the Dania ground. A power line has been brought to the property from the nearest branch, 1000 ft. away. A new plant of machinery has been installed. Work in the shaft has been under way for some weeks with a small force. The depth to which the shaft will be sunk has not been determined, depending upon the dip of the formations which shows small shoots of carbonate of zinc in the Silver King adjoining. These shoots are the objective of the work now in progress. Carbonate is exposed in both the By Chance and Silver King tunnels, but the veins dip under the tunnel levels. The surrounding territory has been little developed and offers a promising area.

Idaho Springs.

At the Portland mine a body of ore has been opened for 500 ft. for stoping on the 1950 level, and it is said to be richer than at higher levels. The ore in the 18th level has been broken down in the stope over 500 ft. in length. Little of the ore has been shipped. The main shipments have been from the levels above. The ore on the 1950 has not been

stoped, but the shoot has been opened and timbered. The company is now raising from the 19th to the 18th level for air and this winter will sink from the 19th to connect with the Roosevelt tunnel 100 ft. below. The Roosevelt tunnel breast is now about 1500 ft. from the Portland shaft and will be directly under it in March or April.

The Independence mill is going ahead steadily and by Jan. 1 will be ready for operation with a capacity of 1250 tons. In connection with this plant is the sampler plant, which will have a crushing capacity of 100 tons per hour. The plants have been delayed some by the inability of machinery companies to fill orders.

In the Bellevue mountain district the Tek Mining & Milling Co., under Manager Weber, has recently struck good ore. In driving the main tunnel to reach a cross vein they broke into a shoot that runs, by several assays: 3.08 ozs. gold and 7 ozs. silver, 10.20 ozs. gold and 11 ozs. silver, 20.06 ozs. gold and 11.70 ozs. silver. The ore carries considerable copper, running from 3 to 12%. The vein matter between walls averages 3½ ft. It is the intention to continue driving on the vein for 600 ft. to intersect with another cross lode which will be cut at 600 ft. in depth. The company has a 10-stamp mill and their own water power.

IDAHO.

Wallace.

The mill of the Empire Copper Mining Co., which owns and is operating the Empire Copper properties, on the Little North Fork of the Coeur d'Alene river, near Enaville, is to be increased from 150 to 300 tons daily capacity, according to Andy J. Devlin, vice-president and principal stockholder, who states that the additional machinery already has been ordered. The crusher department of the present plant has a capacity of 600 tons daily, and the mill was constructed so that additional units could be installed as necessity required. The mine and mill machinery is actuated by a 200-hp. electric motor, driven by current from the Washington Water Power Co.'s transmission lines, and recently a 22-drill compressor plant and a 250-ton filter press were installed. The latter reduces the moisture in the concentrates to approximately 10%, and has effected a material saving in transportation costs. In the last 14 months the company has developed its holdings, formerly known as the Horst-Powell group, from an insignificant prospect to a producing property, and now is shipping at the rate of 3 cars of concentrates weekly to Trail under a long-term contract at a freight and treatment charge of \$8.50. The mill recovery is about 91%, according to the management, and the product averages 18.5% copper. About \$100,000 have been expended in development and equipment, and the company now employs about 60 men.

Burke.

The Hecla Mining Co., which owns and is operating the Hecla mine, a mill of its own at Gem, and has the Union mill of the Federal Mining Co. at Wallace, under lease, has declared the regular monthly dividend, 15 cts. a share, or \$150,000, payable the 20th to stockholders of record the 4th. This will make the payments for the current year \$1,250,000, and will increase the grand total to \$5,005,000, or a half cent more than \$5 a share on the entire capitalization of 1,000,000 that has been disbursed to stockholders since dividends were inaugurated. In the first 10 months of 1916 the company will have apportioned to stockholders \$685,000 more than the total dividend payments in 1915, which were \$565,000, and for the year the company will take fourth place among Coeur d'Alene companies for disbursements—the Interstate-Callahan Co. ranking first, the Hercules second and the Bunker Hill & Sullivan Co. third. The Hecla surplus fund now is in excess of \$550,000, and, despite the fact that improvements to cost approximately \$100,000 have been authorized, it is anticipated that a substantial extra dividend will be declared in December. The company now is treating 450 tons of ore daily in its Gem mill and 300 tons a day in the Federal mill. An addition of 200 tons is being constructed at its own plant, and it is believed that when this is in service that the

Federal mill also will be retained, making the total daily production of milling ore alone not less than 950 tons. In addition the output of crude ore is considerable, and will be increased proportionately as the facilities for reducing the concentrating product are augmented. The total gross income of the company for the 6 months ended June 30, 1916, was \$1,082,587, and the net profit for the period was \$766,887, or \$205,135 more than for the entire year 1915. Production will be much greater for the last half of 1916, and it is probable that the net earnings for the 12 months will be not less than \$1,750,000.

Kellogg.

A special meeting of the stockholders of the Nabob Mining Co. was held on the 2nd and the capitalization was increased from 1,500,000 shares at \$1 each to 2,000,000 shares, ratifying a directors' resolution adopted several weeks ago. A New York syndicate, represented by H. T. Irvine of Spokane, is endeavoring to secure control of the company, according to current report, and it is said that an offer has been made for the increased capitalization and the 250,000 shares of treasury stock for a price considerably in excess of the prevailing quotations. No definite information in regard to the rumored deal can be secured, but it is believed that representatives of the syndicate have been actively buying the stock in the open market for some time.

The grading for the Bunker Hill & Sullivan smelter buildings has been completed and the concrete foundations placed. The O. W. R. & N. Co. is installing sidings to the site from its main line at Sweeny, just a short distance from Kellogg, and active construction will begin as soon as material, now in storage at Kellogg, can be delivered on the ground. It is anticipated that the plan will be finished and ready for service before July, 1917, provided equipment can be furnished by the manufacturers who have the contracts for supplying the machinery.

LAKE SUPERIOR.

COPPER.

Houghton.

Ahmeek has bought of the Denver Rock Drill Co. 20 more of its Dreadnought pattern, making 40 in all. This type of drill, which is similar to the other patterns of the single-man drill, with the exception that it is valveless, has been found particularly well adapted to the rock of this mine. The strip of profitable mineralization, when the Kearsarge conglomerate was opened by the crosscut, was 6 ft. wide. There has not been any opportunity to test it again, as only drifting is being done. The good ground is continuing in both drifts, and has carried from the very first considerable small mass copper.

LaSalle has made to the Ahmeek mill two shipments of rock, which is the overflow from the Franklin, where quite frequently three stamps are used for that mine's own rock, but it has not yet been stamped, as probably a large quantity is being awaited so as to avoid two or three "clean-ups" of the stamps and wash. It is understood that there is some improvement in the yield of refined copper from the LaSalle rock. The fourth stamp at the Franklin has to care for the LaSalle and the South Lake; consequently there is often an overflow.

Algoma's boiler, which was ordered in March, is now on the way to the property, where it will be put in place as soon as possible, and sinking will be resumed. The shaft, when the work had to be stopped, was down about 450 ft., and it was hoped that commercial quantities of the black oxide copper, tenorite, or of native copper, which some thought was indicated by the presence of the black oxide near the surface, would be encountered.

Calumet & Hecla will undoubtedly adopt the flotation process for the fines. Experiments have been carried on by H. C. Benedict, the mill metallurgist, or superintendent of the ore dressing department, for the company, but now it is said that an expert has been brought in from the west, where this process has been developed to a high degree of efficiency,

to aid in its adaptation. It is likely that the plant will be placed on the southern side of the mills, as the space at the northern side will be taken up completely by the large addition that will be made in the spring to the leaching plant, in which there will be installed, when it is finished, two very large leaching tanks and others later; houses are now being moved away for this purpose.

New Baltic has dug out its pit for the shaft about 12 ft. and it has about 35 to 38 ft. to go to reach the top of the ledge, judging from the depth of the overburden in the diamond drill holes that have been driven in this vicinity. A small hoist and a derrick have been placed in position and the work will move along rapidly.

New Arcadian is in quite a long stretch of rich rock on the 1050 level, a little over half way from the shaft to the New Baltic boundary, and the quality and quantity of the copper is about the same as that encountered on the 250 and 900 levels, both of which have been carried to the line; these facts augur well for this lode on that property. The shaft is down 1460 ft. toward the 1500 level, where a crosscut will be cut over to the New Arcadian lode, and also drifts driven on the lode that is partly in the shaft, and which on the levels above has been met with about 16 ft. behind the shaft. At the No. 2 shaft, which is down 150 ft. on the lode supposed to be the Old Arcadian, drifts have just been started in the foot wall, where there is 8 ft. of heavy shot copper. There are now nine drills at work on the property. Men are difficult to get and to hold here on account of the isolation.

Indiana, in the lode supposed to be the Butler, finds some commercial copper, but the most of it is light and flaky. An old trench was used and the lode has been entered for a depth of about 10 ft.; sinking has been suspended to put in the necessary timber. It is too near the top of the lode to tell much about its mineralization.

Lake is gaining slowly in its tonnage, as more men are being added, and now about 7000 tons are being hoisted monthly. The lower levels are at the present time looking better and are giving about the same yield as the upper—26 lbs. The shaft on the Knowlton lode is unwatered for the full depth, 600 ft., and now a hoist is being provided with other work that must be done preliminary to mining.

Adventure has ended the timbering of the shaft through the stretch of about 135 ft., of which the last 50 ft. was partly in rock and partly in quicksand, the latter having been very difficult to control, and is now down to the first level of No. 1, located on the hill. So far pumping has been employed for unwatering, but now the bailing tanks will be used. The water is not yet down far enough for an examination of the mineral contents. The occurrence of the copper here on the Knowlton lode is regular, but it is of low-grade and had run down at this shaft, when mining was stopped here in January, 1908, to 1: lbs., but even this would be profitable at the present prices with the improved methods of mining and milling. This was a first-class shaft, and it had reached the 13th level; its openings are quite extensive and it had installed electric haulage on the 10th level east. If this lode should not prove profitable, an examination can be readily made of the Butler and the other Knowlton and Evergreen lodes, which are making such a good showing at the nearby properties. The mill can be easily put into good condition.

Old Osceola's new ground at the southern end of the mine is "sweetening" the yield so that for this branch of the Osceola Con. the smelter returns are about 17 to 18 lbs. The 39th to the 42nd, inclusive, are all in this good territory, which means very much for the LaSalle; also, as some of these levels have been carried to the line, it is likely that some day one drift will be extended into the LaSalle.

Isle Royale's production last month was about 82,000 tons, which at 14 lbs. a ton, the selling price 26 cts., give as the earnings very neatly \$170,000, or at the rate of about \$2,000,000 yearly. A conservative estimate for the year is about \$1,500,000, or \$10 a share. When more men can be had the tonnage will rise.

Copper Range, on account of the high price of the metal and the impossibilities of securing deliveries of the material anywhere near the agreed upon time, has deferred the

placing of a contract for building the new Trimountain mill until next spring at least. The tonnage at these mines is now keeping up to the normal.

Quincy, which did not find the copper at the No. 9 shaft to be of commercial values, either in the shaft itself, which was carried down about 2400 ft., or in a drift that was carried over from No. 8 at about the 40th level, is now extending the 55th level and is about 500 ft. from No. 9 in a better ground. Several other levels are being driven in this direction. The mineralization seems to dip quite sharply to the north and the indications are that the profitable ore body is now being entered. When it is found there will be quite a large mine on this end of the property, as the depth is good.

Winona is getting some rich copper at King Philip shaft No. 1, which will aid greatly in raising the yield. All shafts are running night shifts.

Houghton Copper has so far 140 ft. of good ground opened up in its northern drift on the 12th, or bottom level. On account of being obliged to hoist the rock in the winze to the 6th, where it is trammed 250 ft. and then hoisted to the surface, only one drill can be used on this level and that has to divide its work between the drift and the west vein. Occasionally some spots of good copper are found in the latter, but both here and in the drifts on the 4th level, the copper is scarce. The stoping on the 6th level is in profitable ground. It would seem that the future of the mine is on the Superior lode at depth.

Flint Steel, located between the Michigan and old Lake Superior properties on the southwest and the Adventure and Mass on the southwest, and comprising the eastern half of the northeastern quarter, and the whole southeastern quarter of Sec. 11, together with the Sec. 12 entire, will begin unwatering its old workings right away. New York parties have taken option on this property from the Ferguson heirs, also of New York, and will give it a thorough exploration. It was last worked in 1875, 830,000 lbs. of refined copper having been obtained from a fissure vein; it had three connected shafts. It has the Evergreen and Knowlton series of lodes most advantageously situated. The fact that Flint Steel has the Butler lode, which at the Mass on the north and the Michigan on the south are finding good values on this lode, seem to make it a success at the start; then it has the advantage of the old shaft, which will aid greatly in the exploration, as it is probable that crosscuts can be driven easily. The work will be under the direction of Supt. Samuel Brady of the Michigan, who has made a thorough study of the lodes of this part of the Keweenaw series.

IRON.

Iron River.

Progress is now being noted at the Forbes, which is a Jones & Laughlin property, with C. T. Kruse as general manager, and E. Corey, mining captain. The new system of open stopes is being well carried out with safety to the employes and with respect to the interests of the fee owners as well as to the company's side. Both the settling plan and the open stopes are being observed and operated, some of the deposits not being such that the caving plan can be practiced profitably.

Negaunee.

Under Superintendent Jackson the Athens shaft is being pushed and is now down 2000 ft. The work of running crosscuts to the ore body will also be rushed and when things are completed the Athens will be one of the deepest properties in the iron fields.

Work is being rushed to get out as much ore as possible at the Iron Mountain Lake mine before the close of the season. About 25 men have been employed at the property during the summer and Manager Kruse is desirous of adding about 40 more. There is considerable ore on stock at the mine and Kruse will make an effort to ship most of it this season. The shaft sinking operations were suspended some months ago. It is thought they will be resumed this winter. A small force of men has been at the property this summer to keep it in condition for slipping operations.

The work of opening the Holmes mine, which was started this spring by the Cleveland-Cliffs Co., is progressing. The

headframe is being erected by the Worden-Allen Co. When completed it will be 145 ft. high. There will be three crushers in it, two of the No. 5 size and one of the No. 8 size, with crushing rolls included. Because of the fact that both soft and hard hematites will be mined there will be separate pockets and chutes. There will be railway tracks on both the east and west sides of the shaft, with six pockets on each side. The concrete for the bases of the crushers is now being placed. The crushers are on the ground. Exterior work on the office and engine house has been finished. Work on the shop building and boiler house has commenced and work will be started on the change house soon.

MISSOURI-KANSAS.

Webb City, Mo.

McDonald Bros. are developing a lease in the Prosperity camp and during their development have sunk eight drill holes, four showing a soft ground formation from 190 to 240 ft., and four others showing a run of sheet ground ore. In sinking the shaft it was found that the run of soft ground ore came in at 150 ft., which is 40 ft. higher than shown by the drill records. The shaft is now down 196 ft. and the ore taken out is believed will run from 10 to 15% zinc. Preparations are being made for the erection of a milling plant, to be completed by the time the underground is opened up.

G. A. Barnett of Joplin and J. W. Grounds of Kansas City are building a 150-ton mill on a lease in the Duenweg camp and 14 drill holes have been put down, 12 of them showing good ore at 130 ft. Four shafts have been put down, which show 20 to 35-ft. faces of silicate ore. Considerable drifting has been done, and preparations are made to keep the mill running steadily.

Joplin, Mo.

With the clearing up of power conditions in the Joplin field there has been a resumption of mining operations in a number of mining camps, which have been most severely affected for a lack of coal and the shutting off of the electric current. Barring a lack of water for milling purposes, there will be no reason for any mine now operating at the present time, except the difference in the cost of production and the prices being paid for ore, not providing a reasonable margin of profit necessary for operation.

Among those resuming is that of the A. W. C. group of mills west of Joplin. Four of the five properties in this group were started Monday. Part of the difficulty this company has had has been the lack of water. This has been remedied by pumping some adjoining ground. In the Belleville camp, west of Joplin, the Lucky George Mining Co. has been compelled to move its mill to a new site, owing to the caving ground. This property has a large modern plant, and had only gotten well under way when the caving ground threatened the mill and mining operations were abandoned temporarily. A new mill will be erected and operations resumed at an early date.

On the W. A. Campbell land at Belleville the Eaglewood Mining Co. is erecting a new 250-ton mill. The company has drilled five holes and sunk three shafts, opening up some excellent ore at the 70-ft. level. At a still lower level ore running as high as 20% has been discovered by drilling. It is expected that the company will be able to turn out concentrates by the first of November.

A new prospect has been opened up by the Goodrich Mining Co., operating a lease on the old Sherwood mine northwest of Joplin. The old Sherwood mine operated at the 80-ft. level, took out a very rich deposit of ore at that depth in one portion of the 40-acre tract. The Goodrich Co. sunk its shaft to the 100 level, and is now taking out ore estimated to run 12%. For the present the ore is being handled over hand jigs, outputting about 8 tons per week.

Graham, Mead & Co., operating on a 20-acre lease on the Campbell, southeast of Joplin, this week, made a rich strike of shallow zinc ore while deepening a shaft in order to obtain water for the silicate mine. The ore deposit was struck at

-64 ft., and while the shaft is only 2 or 3 ft. into the ore, the ore so far taken out, it is believed, will run 12%. The ore occurs in soft ground and hand jigs will be used for cleaning it. Those interested in the mine are J. M. Graham, G. J. Graham, J. E. Walker, Harry Mead, Amos Freeman, Jack Ammerman, of Joplin, and J. M. Berriam, Coffeyville, Kan.

The Bonnie Bell Mining Co. lease at Thoms Station on the land of the Mexico-Joplin Land Co. is now getting the mine opened up and expects to be able to make a carload of concentrates weekly within 30 days.

A company, composed of Ed Lockhard, Roy Carney, R. Cox, A. G. Pickens and Lew Jones, obtained a lease upon the land of Mrs. S. B. Jones, southeast of Joplin, and the same day moved a drill rig upon it, which within the day struck a 7-ft. run of lead ore at 38 ft. level, and on the day following the company had sunk a shaft 7 ft. deep. The operators expect to have the shaft into the ore this week, and be regular producers the next.

Galena, Kans.

On the Paige land south of Galena the Double Lew Mining Co. has started the erection of 150-ton concentrating plant on a 12-acre lease just south of Wayland lease. The company has already produced approximately \$85,000 of ore since the first of the year, all of which has been cleaned over hand jigs. The ore to be handled is found at from 50 to 65 ft., two shafts being operated. The ore has been running about 10% and the concentrates are high-grade. Drills show the existence of ore down to 120 ft. Those interested in the company are: J. T. Wayland, O. H. Wayland, Walter Wayland, of Girard, Kan., and L. H. Phillips, of Galena.

MONTANA.

Butte.

Butte is soon to be made the headquarters for one of the largest and most thoroughly equipped "mines safety" stations of the federal bureau of mines. In this city will be located one of the new mine rescue cars of the government and between six and ten men of the federal bureau's staff will be stationed here. In co-operation with the Montana School of Mines an office for the men of the federal bureau will be established here. This will be used also by the bureau's representatives who are traveling through this section of the country.

The Lexington mine, a valuable zinc property located in the Walkerville district and for several years a highly profitable silver property, is to be sold at auction in this city Nov. 1. In the days of F. Augustus Heinze the Lexington belonged to the La France Copper Co. and a few years ago it was taken over by a concern known as the Atlantic Mines Co. The Atlantic Mines Co. was dissolved some time ago and the sale is for the purpose of making a final disposition of the assets. For some time the property has been under control of the Anaconda, who offered a sum equal to about \$12.50 a share for the property and it is understood this offer will be formally accepted at the sale Nov. 1. Heinze organized the La France in 1905 with a capitalization of \$7,000,000 and an authorized bond issue of \$2,000,000. The Lexington has a 3-compartment shaft, 1450 ft. deep, and is connected on the 600 level with the Alice mine. With its new zinc-treating properties at Anaconda and Great Falls the Anaconda will be in a position to treat the zinc ores of the Lexington at a good profit.

The mines of the Butte district yielded 30,960,000 lbs. of copper in September. Of this amount 29,400,000 lbs. was produced by the Anaconda and 1,760,100 by the East Butte. The monthly production of the Anaconda company for the year was as follows: January, 23,200,000 lbs.; February, 23,300,000; March, 26,600,000; April, 33,300,000; May, 30,000,000; June, 28,100,000; July, 28,200,000; August, 28,800,000; September, 29,400,000; total, 233,900,000 lbs. The following is the East Butte production by months: January, 1,060,000 lbs.; February, 1,277,000; March, 1,306,000; April, 1,501,000; May, 1,517,440; June, 1,639,560; July, 1,893,120; August, 1,849,120; September, 1,760,100; total, 13,893,340 lbs. Butte's total pro-

duction for the nine months is 247,703,340, or close to a quarter of a billion pounds.

Clinton.

Spokane men have formed a tentative corporation and taken a bond of \$30,000 for 2 years on the Klondike group of four claims 2 miles from Clinton, Missoula county, it is announced by Bob Mabry. It is proposed to develop a ledge giving large promise of copper and silver. "Preliminary work has been proceeding for several months on an option, the purpose being to determine the possibilities before investing," said Mr. Mabry. "Ore was exposed in the explorations of J. A. Weston and U. S. Swartz, from whom we purchased. We continued the investigations with a prospecting tunnel and a 40-ft. drift, the latter exposing a vein 5 ft. wide between granite that contains a streak 10 ins. wide having high values in copper and silver. The lower tunnel, in 300 ft., is within 100 ft. of the locality where the ledge should be cut. Samples from the face of the upper tunnel show values of \$60 to \$106.41. The latter is represented by 18.8% copper and 7.2 ozs. silver." The officers and stockholders are Dr. W. M. Newman, president; J. P. Dillard, secretary-treasurer; David Holzman, Samuel Edelstein, E. A. Moye, O. A. Broyles, J. P. Acoam and Mr. Mabry.

Troy.

Active mining operations will be begun about Nov. 1 by the Snowstorm Mines Con. Co., according to an official report received recently from President Leo Greenough by William A. Nicholls, president of the Spokane Stock Exchange of Spokane. More than 550 men now are employed constructing a mill, hydro-electric power station and a railway to connect the mines and mill and the shipping bins on the Great Northern tracks, near Troy. It is estimated that there now are approximately 400,000 tons of ore ready for extraction, assaying 7% lead, 8% zinc and 3 ozs. silver. "The concentrator has a capacity of 300 tons daily, but this can be increased to 500 by the addition of tables and tube mills," says the report. "Tests indicate that an extraction of 85 to 90% of the lead and silver may be expected, and, although the zinc ore is refractory, we are confident of an extraction of at least 40%. The ore will be reduced to slimes, and then treated by flotation. The greatest development has been done on the Banner & Bangle vein, which has been opened by six tunnels for 2500 ft., giving a vertical depth of 1100 ft., and all the faces are in ore. Tunnel No. 4 has been run on the vein for 600-ft., exposing 3 ft. of ore containing 13.4% lead, 11.2% zinc and 5 ozs. silver. Tunnel No. 5 has been run on the vein 1040 ft., exposing a body 3 ft. wide, containing 5.3% lead, 7.7% zinc and 2.6 ozs. silver, and tunnel No. 6 has been run on the vein for 2450 ft., exposing a body 2.2 ft. wide, containing 8.1% lead, 8.7% zinc and 3.8 ozs. silver. Power will be supplied by a hydro-electric plant at Lake creek. Water will be impounded by a 40-ft. dam and conveyed by a 200-ft. flume, from which a minimum of 2500 hp. may be developed. The first installation will generate 1500 hp. Power will be transmitted 1½ miles to the mill and 7 miles to the mine. A 17,000-ft. flume is under construction between Callahan creek and the mill. The water will be used for washing ore, fire protection, domestic purposes and for driving some of the machinery. Transportation between the mine and the mill will be provided by a railroad 5½ miles long. It is built on a 36-in. gage. Steam will be used at the outset, but electricity ultimately. The estimated cost of the construction, equipment and installation is \$450,000. The \$560,000 available should be sufficient for the operation until the property is on a paying basis. Part of this money was obtained from the treasury of the Snowstorm Mining Co. and the rest through the sale of stock and on long time notes. An option and a long time bond is held on the property, which is comprised of 25 mining claims, seven mill-sites, two power sites and five water rights, in addition to which the company has acquired 260 acres at Troy for a mill-site, and 220 acres for a power plant. The lease and bond calls for the payment of \$225,000, of which \$75,000 will be due Nov. 20, 1920, and \$150,000 a year later. A royalty of 10% will be paid on the net smelter returns."

Helena.

At a meeting of the Cruse Con. Mining Co., operating just west of Ft. Wm. Henry Harrison, in the Grass Valley

district, James J. Cruse, Edward Phelan, J. S. Scott, Claud G. Wilson, Wm. C. Sweeney, R. A. Weisner and L. S. Ropes were elected directors to act until the regular annual meeting of the stockholders in January. James J. Cruse, president; Ed. Phelan, vice-president and treasurer; R. A. Weisner, secretary. At a meeting of the directors it was decided to put on two shifts on the Looby shaft and to erect a new bunk house at the mine. Ore recovered in sinking this shaft, an incline on the vein, is more than paying for the costs of the work.

The vertical shaft of the Rock Rose Mining & Milling Co. on the Dandy claim is being sunk to the 200 level. From the surface to 150 ft. the shaft has carried a vein of quartz and pyrite with gold and silver values. At this depth the porphyry dike on the south of the shaft feathered out, bringing in another vein on its foot wall, joining the shaft vein. At this point lead and silver values came in, largely increasing the value of the ore. At the present bottom, this vein has a slightly southern dip, which has carried it outside the shaft timbers. The main vein of the Dandy lies to the north of the shaft, at the 100 level, being 23 ft. from the shaft, where it carried high values in lead, silver and gold. It is for the development of this that the shaft is being sunk, the south vein being an unlooked for asset. Evidence of oxidation and replacement are noted to the present depth. The formation is slates, diorite porphyry and hornstones, characteristic of the Marysville district, and in close proximity to the underlying monzonite, exposures of which occur in the Scratch Gravel hills, just to the north and in the Ten-Mile basin to the south. The district is attracting considerable attention, locally. The Rock Rose is controlled by the Cruse Con. Mining Co.

At the Carbon Hill, a mile west, the shaft is down 200 ft. on the inclined vein. Drifting will be commenced at this level. This vein dips to the west, whereas the Looby and other north-south veins of the eastern portion of the district have an eastern dip. The Carbon Hill is in the diorite porphyry. Silver, lead and gold are the values in this vein, some lanches being of exceptionally high grade. The Carbon Hill is at a higher altitude and leaching is in evidence to the present depth.

The outlook for the Grass Valley district is very bright, now that development in depth is being undertaken along definite lines. Lying but a few miles from and in sight of Helena, the district is favorably situated for economical mining. The Northern Pacific railway passes within from a half to 2 miles of all parts of the district, and electric power lines are within a few miles.

Marysville.

During the past summer several properties have been under investigation by eastern capital, this, in the way of prospecting, developing known veins and reopening old mines. The result has been the conclusion of negotiations upon all options investigated. Among these, the Annie Dillon, under the organization of the Marysville Gold Mining Co., has been taken over through its stock holdings, and becomes the organization and assignee for all options on the remaining groups. The groups, all of which have been assigned to Maurice Eisenberg of New York and by him to the above company, comprise the Honey Comb, five claims, the Blue Bird and Hickey, eight claims and mill site; the Spokane, three claims; the Lynch, two claims; the Mt. Pleasant claim and the Fountain Head claim. Work will be carried on during the winter developing and prospecting new territory. The Hickey crosscut is being pushed north into the Mt. Pleasant-Honey Comb territory, and work will be started on the Spokane, into the same, and the Blue Bird-Hickey territory, tapping these at from 550 to 750 ft. depth, in a distance of about 3500 ft. from the portal.

The St. Louis Mining & Milling Co. is preparing to make some alterations in its mill and equip with electric motors. With this completed operations in mine and mill will be resumed. The company has considerable ore available in the old stopes of the Drumlummon, some virgin ground to stope and considerable unprospected territory of exceptional promise, insuring continued operations.

The Golster and Shannon of the Barnes-King Development Co. have settled down to operation and development,

the Shannon delivering its ores to the Gloster mill over a 13,000-ft. aerial tram over the sides of Mt. Pleasant and Mt. Belmont.

Chas. Longmaid and associates have cleaned up their season's work, cyaniding the tailings from the old Penobscott mill, with satisfactory results. They expect to move their plant to the lower dams in Lost Horse gulch next season.

Tower and Templeman have their cyanide plant complete and in operation on the Bald Butte tailings. Owing to the late and unusually bad spring, they were greatly delayed in getting their machinery in, causing a late start.

Lessees have been assigned sections in the Bald Butte mine and the company has let a contract to drive a crosscut on No. 4 tunnel level to intercept a strike of high-grade ore made on the surface during the past season. Should this develop sufficiently to justify, the mill will be started up; also handling lessees' ore.

NEVADA.

Goldfield.

Developments on the 300 level of the Great Bend have opened three shoots of good ore and the management is arranging for shipments. The first shoot is about 3 ft. wide and has been opened for 115 ft. It is of good milling grade. The second shoot is 14 to 25 ft. wide with seams of high-grade ore accompanying the leaner material. The third shoot was opened last week in the east drift. It averages 2 ft. wide and assays up to \$160 in gold and \$1.50 silver. Plans have been prepared for a flotation plant, and the shaft will be carried deeper and extensive lateral operations undertaken in virgin territory. The Great Bend is located in the Diamondfield section of the Goldfield district.

At an approximate depth of 930 ft. the shaft of the Silver Pick has entered shale after passing through an ore channel 30 ft. thick. Sinking continues to tap the ore channel in the shale-alaskite contact, recently indicated by the core drill. As soon as this point has been gained crosscuts will be extended to prospect both contact zones. Prospecting with the Calyx drill has been started about 800 ft. west of the shaft.

The shaft of the Cracker Jack is being retimbered to the 320 level and from this point drifts will be driven to seek the two veins developed near surface. Development of the rich shoot encountered at a depth of 120 ft. has been resumed. The mine is splendidly equipped for deep work. H. G. McMahon is manager.

The south drift from the 350 level of the Sandstorm-Kendall is advancing rapidly and is expected to intersect the Loftus-Davis shoot within 30 days. This shoot was one of the richest ever worked in the district, but was only worked to a depth of 70 ft. The Sandstorm-Kendall is the oldest mine in the district and was one of the first to claim recognition.

The Goldfield Con. has arranged to abandon the Mohawk shaft and production in future will be by way of the Combination and Clermont shafts. The new underground electric haulage system will facilitate ore deliveries to the shafts at low expense. During the past few weeks considerable rich ore has been uncovered in the Mohawk mine, averaging around \$125 gold. Developments in the deeper levels of the Laguna and Red Top are reported satisfactory, while new ground in the Mohawk and Combination is yielding good ore. New equipment for the flotation plant is expected to arrive shortly.

Manhattan.

Most of the equipment for the new reduction plant of the White Caps Co. is on the ground, or in transit, excepting the roaster, which is being constructed in the east. The management expects to have the plant in operation by Feb. 1, and is engaged in blocking out large reserves in the 310 level workings. Deepening of the shaft will commence in 30 days.

The Union Amalgamated Co. has arranged to deepen the main shaft to 625 ft. and to press extensive developments

from the new level. Grading for the compressor has started. The mill is running steadily and if work on the 625 level proves satisfactory the plant will be moved to a point below the Bath mine. It is at present a mile from the property.

Tonopah.

The miners of Tonopah have filed a demand for a wage advance of 50 cts. per day, and the matter is being considered by the Mine Operators' Association. The men state increased living costs warrant the advance asked, together with the fact that the silver-producing companies are earning large profits.

The new station on the 1500 level of the Gypsy Queen has been completed and drifting to strike the vein opened in the winze from the 1350 level will soon commence. The drift is expected to also open the gold ledge which was encountered at a depth of 1470 ft., but development was prevented by an inrush of water. The work is being followed with much interest, particularly in view of the late discoveries of gold-bearing shoots on the 1400 level of the Belmont and 1050 workings of the Rescue Eula. Apparently the gold-carrying formation extends back of Mt. Oddie in the form of a crescent.

Pioche.

For the first time in 20 years the 1200 workings of the Yuba mine have been opened, the work being accomplished last week by the Meadow Valley Leasing Co. Ore of excellent grade is reported to be showing and it is believed the old producer will shortly take its place among the big yielders of Pioche. It has a productive record of \$5,000,000.

NEW MEXICO.

Mogollon.

September has been another excellent month for local operators. The Socorro Mining & Milling Co.'s properties produced 3300 lbs. of gold and silver bullion and the Mogollon Mines Co., operating the Last Chance mine, shipped 2700 lbs. for same period, a total of 3 tons of precious metal for the 30 days. In addition, each company shipped to smelter at El Paso high-grade concentrates in value about equal to the bullion product, latter going direct to mint.

The development companies also met with substantial encouragement, particularly the Oaks Co., in the continued improvement of ore body recently opened on the Queen vein on Clifton property, from which regular shipments to custom mill by burro were maintained. Another young mine, the Eureka, continues to sack high-grade ore for shipment to smelter, while results of work on a number of claims by their prospector owners lends energy to the task and a faith in the outcome that is unsurpassed in any other line of pursuit.

Supt. E. L. Perkins of Mogollon Mines Co. is conducting a series of flotation experiments on local ores and the results thus far justify the belief that a greatly simplified treatment with a substantial reduction of costs may be evolved. The Mogollon district has a recorded production of upwards of \$15,000,000 to date, largely from an average grade of \$12 ore. This activity has extended over a period of many years, and with comparatively high costs necessitating more or less selective mining methods, the camp has an immense tonnage of lower-grade ores in reserve. With the reduced costs of operation that will follow hydro-electric installations and the eventual adaptation of oil flotation treatment now in prospect, these ores should yield quite as much profit as the higher grades have in the past.

OREGON.

J. W. Larkin, A. Prader and E. L. Prader, Spokane, made an examination of the Overholt ground on Miller mountain. This property has about \$8000 worth of development work on it and the ore bodies are well developed.

Grants Pass.

The Grants Pass Hardware Co. has purchased the Ida mine of the Granite Hill group. The Waldo Mining Co., who

recently bought out the plant of the old Mt. Pitt mine, has a crew of wreckers at work taking down the mill, part of the machinery being hauled over to the Waldo mine and the remainder offered for sale. Manager P. B. Wickman of the Alameda mine has a crew of men at work constructing a road from the Copper Eagle mine, which he will develop. There are already several thousand tons of ore blocked out. It is expected that teams will be at work hauling it out within the next two weeks. The ore will be shipped to the Tacoma smelter. Loads of steel pipe are being hauled to Louise Creek valley for reopening the Granite Hill placer when the rains begin. Upwards of \$60,000 has been extracted previously. A shipment of 5 tons of high-grade from the Neil Success, was sent to Seattle as an experiment to determine the best method of reduction. Some of the ore was said to run over \$600. There is a good quantity of ore on the property.

SOUTH DAKOTA.

Lead.

Sinking has been resumed at the property of the Custer Peak Co. in a shaft which was previously put down 250 ft. The installation of a compressor and a new boiler, giving the plant a boiler capacity of 200-hp., has been completed. The sinking was commenced a few days ago and about 10 ft. have been added to the depth of the shaft. Two shifts are worked. It is the intention to employ three shifts in the sinking as soon as necessary arrangements can be made. The water is being satisfactorily handled with a No. 9 Knowles pump, which is part of the new equipment. The present plans include sinking the shaft to a depth of 500 ft. Here there is reason to believe the grade of the copper-bearing ore will have advanced to a commercial value. This expectation is based on the betterment of the grade from the 150 level, where copper was first noticed in appreciable quantities, to the 250 level, where the values showed a material increase. The ore body has a width of more than 100 ft.

After idleness for several years development has been resumed at the Puritan and shaft sinking begun. The initial work will consist of putting the main shaft down to a depth of 250 ft. Connection may then be made with other workings, and afford a practical means of mining ore from a ledge which has already been partially developed. An additional depth of 60 ft. will accomplish this. Aside from high-grade ore in the vertical, the ground contains an immense blanket of quartzite that will afford a supply of milling material. This blanket has an average depth of 28 ft. and has been prospected at eight or ten points in widely separated locations on the property. It is reliably stated that the quartzite will average between \$3 and \$4 in gold, silver and lead and under present treatment methods should yield a profit. Its development will require considerable additional mining, in order that it may be opened from underneath. The 20-stamp mill is in good condition and is expected to serve in handling the mine product.

UTAH.

Eureka.

A cave 100 ft. deep has been opened at the Eureka Lilly. It was encountered while a winze was being sunk on a fissure which was highly mineralized. The winze was sent down on an incline along the hanging wall. At a depth of 110 ft. below the 500 level the cave was encountered changing the dip of the fissure to vertical. It is the intention to sink the main working shaft, now down 500 ft. While waiting for new equipment they decided to sink a winze from the 500. This winze is located about 120 ft. from the shaft and had reached a depth of 110 ft. when the cave was located. Most of the ore mined at this property came from the 400 level. Operations at Tintic Standard have revealed deposits at greater depth and on the strength of this the future plans

of Eureka Lilly are to attain greater depth and the expected ore bodies.

Good ore, in places 4 ft. thick, is showing in the shaft of the Eagle & Blue Bell. The shaft is now down about 50 ft. in the new drive below the station at the 1875 level. It is the purpose to send the shaft to the water level, probably near the 2100 before cutting a new station and prospecting the new body at this depth. At the new station on the 1875, a drift is being sent out to connect with the winze sunk from the 1700. Another drift is going out in the opposite direction to prove the extent of the ore in that quarter.

By Nov. 1 the Tintic Milling Co. will have its new Holt-Dern roasters installed and started on an increased production. The addition of the roasters and other changes which are being made will bring the capacity of the mill up to about 300 tons per day. Already some of the mines are making preparations to supply the plant with ore. A good part of the ore will come from the Dragon and Iron Blossom, although the Colorado, Swansea and others will be benefited. Some of the copper ore in the Iron Blossom, while it is so rich that it cannot be considered a milling product, may possibly be sent to the mill, because it is a class of ore that is needed and on which a splendid extraction of values can be made.

Alta.

The Old Emma Leasing Co. is now installing a 500-gpm. pump to be operated by electricity. This will be used to dewater the shaft through the Bay City tunnel. Rails and other equipment have been ordered and by Nov. 6 it is expected that a drift of 100 ft. will be made from the shaft and the ore opened for shipment. By the time the property is ready to take out ore it is believed that the new railroad into Alta will be completed. A spur can be put in to the Emma bins and a large saving made on transportation. The third drill hole, No. 6, encountered the ore and has since been driven through the body. The three holes put down have demonstrated the presence of the ore body. A number of other drill holes will be put down but they will be used to demonstrate other geological features. The second level in the shaft below the Bay City tunnel is down 225 ft. It is expected that the pump can lower the water to that depth in 2 weeks. Power drills will be put to work drifting when the level is reached. The first week in November, according to calculations of engineers, the Herzig drift should reach its objective and pass through the Montezuma fault 650 ft. further to the northwest. It is being driven to encounter the downward extension of the ore body which was mined in the Gunderson stope in the Burgess Tunnel workings. The Gunderson was the largest stope in the old Vallejo mine and is reputed to have produced a big tonnage of high grade but was terminated against the Montezuma fault. Plans for consolidating the Old Emma and Emma Copper are now being negotiated.

Park City.

With some of its machinery on the ground and all buildings under cover it is expected that Judge Smelting will have its new plant ready for operation by January.

At the Iowa Copper ore being followed in the incline, which is improving in value at depth. A plan was decided upon which will mean the collecting of sufficient money each month to continue development work. In addition to this stock will be put on the market and if sales justify machinery will be installed.

John Nichols and associates, who have a lease on the Hog Pen tunnel, have been driving 6 months without results. This week ore was broken into. Since finding the streaks of ore no mining has been done, it being necessary to put in air pipes. The tunnel is above the No. 2 shaft, where high grade ore was found practically at the grass roots.

At the Ontario new ore reserves are being found and conditions are generally favorable. Every other day a car of ore is shipped. More is being piled up awaiting treatment, because the valley smelters cannot handle it at present.

Daly Judge Extension is equipped with a gasoline hoist, bunkhouse, blacksmith shop, etc. Three men are at work, John Hickson in charge. Work is being done in a shaft down 120 ft. and they expect to break into pay ore with every shot.

An 18-in. fissure has been cut from which is being taken good matter. The formation and dip are favorable. The directors are planning to finance so that work can be continued all winter.

Atkinson.

The new mill of the Big Four Exploration Co. has been completed and is now shipping a car of concentrates a day, though there is some shortage of cars. The product consists of lead-iron and zinc concentrates. The mill is rapidly being brought up to its capacity and is now treating an average of 750 tons of tailings per day. It is expected within a short time the mill will be handling 1000 tons per day. At the present rate of extraction the company is earning \$25,000 per month, or an equivalent of 6 cts. per share per month on the outstanding stock. With modifications that are being worked it is understood that the earnings will be increased. During the summer season the management has had a crew of men at work pilling up tailings. These will be treated in the mill during the winter months, all plans having been completed for keeping the mill running constantly. There are 1,000,000 tons of tailings to be treated, on which the company holds a lease for 8 years. Three shifts are being employed.

WASHINGTON.

Spokane.

The Chloride Hill Mining Co., capitalized for 1,000,000 shares at \$1 each, has been organized by Spokane men to take over and develop the old Santiago silver mine, on the Columbia river, 2 miles from Hunters. E. G. Ross is president and R. B. McClary secretary-treasurer of the new corporation, and, with J. T. Young, Hunters, compose the directorate. The property is one of the oldest locations in Stevens county, and was fairly well developed by former owners. "With silver at present price and the introduction of automobile trucks this property can be put in the shipping class practically at once," according to Mr. McClary. "There is about 10,000 tons of ore on the dumps, from which several cars of shipping product can be sorted. This will be done at once and we believe the property will pay for its own further development. There is a ledge on this property 5½ ft. wide, with an 18-in. strip that goes 80 ozs. silver. The rest of the ledge runs about 20 ozs. This is shown all the way down in a shaft 87 ft. deep and practically the same ore is found in the 240-ft. tunnel run in on the ledge. On the surface there is an ore shoot 700 ft. long that goes \$20 to \$35 silver, and is about 22 ins. wide. Former owners hauled ore to Davenport at a heavy cost. We can bring it out to the same point at much less expense by using auto trucks, or we can ship it by barges down the Columbia to the nearest railroad."

Deep development of the Great Western and Last Chance properties, near Northport, under lease and bond for the past year by Norman Mines Co. of Spokane, has proved disappointing, and operations will be abandoned in a few days. The company was organized over a year ago and in August, 1915, secured from George Thomas, of Colville, a lease and bond upon the Great Western group for \$20,000, running until 1918, with royalties of 15% applicable to all payments. Operations disclosed a large body of zinc carbonate ore above the main tunnel level, at a vertical depth of 85 ft., and under stimulating effect of high spelter prices prevailing early this year, heavy shipments were made to Edgar Zinc Co., Donora, Pa., and Kulsa Spelter Co., Kulsa, Okla. Approximately \$25,000 worth of zinc ores, averaging around 24%, was produced from a body about 250 ft. long mined to the surface from the tunnel level. A gasoline hoist was installed and a winze put down in the ore body at a point where it showed a width of 20 ft. For approximately 40 ft. the showing continued to be favorable, but from that point down to the 100 level no pay ore was found. The Last Chance group adjoining Great Western on the southeast was taken over under lease and bond for \$30,000 from the Jupiter Lead Co. last February. Under former ownership the property had produced approximately \$500,000 worth of lead ore,

and it was believed that the extension of this large ore body could be developed. While several excellent showings were uncovered in the old workings after they had been retimbered, none persisted for any distance and no evidence of continuation below the present workings was found. As a \$3000 payment falls due this month, the directors of the company decided that it would be unbusinesslike to meet it. Until final settlements are received from smelters and all accounts made up for the month of September, no financial statement can be issued to stockholders. All indebtedness will be retired, however, and it is possible that a small cash surplus will be left in the treasury. Another property may be taken over, but no definite arrangements have yet been made. In such event all small stockholders will be carried for interests identical with present holdings and a treasury fund created by stock donations from present control. The officials of the company own practically nine-tenths of the outstanding capital stock, less than 75,000 being held by small owners in this city. The Norman Mines Co. is capitalized for 1,000,000 shares at 10 cts. each, of which about 100,000 still are in the treasury. The officers are James A. Welch, president and general manager; H. R. Welch, vice-president, and Sidney Norman, secretary-treasurer.

WISCONSIN-ILLINOIS.

Platteville.

Deliveries of ore for the month of September were reported, by districts, as shown.

Districts.	Zinc, lbs.	Lead, lbs.	Pyrites, lbs.
Benton	28,766,000	386,000	1,384,000
Galena	7,200,000	118,000	874,000
Mifflin	5,480,000	84,000
Hazel Green	4,326,000	60,000
Cuba City	3,796,000	2,600,000
Linden	3,338,000	156,000	240,000
Platteville	3,004,000
Shullsburg	2,754,000	172,000
Highland	1,592,000
Montfort	518,000
Potosi	334,000
Mineral Point	262,000	4,254,000
Totals	61,370,000	976,000	9,352,000

All previous records established for the field were broken in September. Shipments were the highest ever published. Recovery of zinc concentrates were highest, with a complete summary of 25,000 tons. High-grade refinery zinc ore direct to smelter also exceeded any previous mark, over 15,000 tons leaving the field. A total of 761 cars of zinc ore reached track for the month, 30,685 tons. The New Jersey Zinc Co. shipped 76 cars of high-grade separator ore to DePue, 1521 tons. The reserve at the close of the month, conservatively estimated, showed 7500 tons blende all grade on hand; 1000 tons lead ore and 15,000 tons iron pyrites.

The Block House Mining Co. has put on two shifts. A magnetic separating plant operated in connection with the mill is yielding the highest grade of ore of the field—62% zinc. The Grant County mine is the third low-grade producer to suspend operations within the past 3 weeks. Sixty men were thrown out of employment. Superintendent J. A. McCullough of the Vinegar Hill Zinc Co., with offices at Galena, has been transferred to this point. Mann & Harding Mining Co. has resumed operations. Lee Hinkins has been appointed superintendent. The M. & A. Mining Co., operating the Big Tom mine at Rewey, has a new rig. Shipments are expected soon. About \$35,000 has been expended by the new corporation. The regular annual meeting of the stockholders of the Wisconsin Zinc Co. will be held at 85 Exchange St., Portland, Maine, on the 17th.

Klar-Piquette sent in 2 cars of cleanup stuff, the mine being shut down for good. East End sent 2 cars to Galena, 86 tons; Star Mining Co. to LaSalle, 1 car high-grade, 44 tons; Hodge mine to National Works, Cuba, 4 cars, 172 tons. No returns came from Hazel Green or Potosi camps.

Returns for the field for week of 7th show 116 cars of zinc ore, 4530 tons, a considerable falling off over several previous weeks; 4 cars of lead ore, 153 tons; iron pyrites, 12 cars, 721 tons. The gross recovery crude concentrates were

light, only 3540 tons being reported. Net deliveries of high-grade refinery ore to smelters, 2654 tons. A gain of \$2 per ton for base zinc ore was registered, standard and top grades going at \$60 base, with the range down to \$50 on ore as low as 54% zinc content. Lead ore held at \$75; base 80%.

Shullsburg.

The only producer to report last week was the Winkill—8 cars to Galena. Reserve ore was found in bin at both the Rodhams Mining Co. and the Oliver Mining Co.

Mineral Point.

Receipts of crude concentrates at the Mineral Point Zinc Co. for 7th totaled 31 cars, 1155 tons; cars of this came from independent operators.

Montfort.

Eagle-Picher Lead Co. covered offerings on O. P. David Mining Co. zinc ore, 2 cars going to Collinsville, Ill., last week, 90 tons. This buying concern was active during September.

Cuba City.

National Zinc Ore Separating Co. report 19 cars raw ore delivered to works week of 7th, 750 tons. Shipments high grade to Illinois Zinc Co., 4 cars, 137 tons; to Granby Con., 7 cars, 265 tons. Linden Zinc Co. lessees, Campbell Separating Works to Lanyon Zinc Co., 2 cars, 75 tons. Utt-Thorne Mining Co. purchased the Big 8 mine, buildings and machinery. A new plant is also being provided for the Lawrence mine. Two new plants and one small separating plant are being supplied for Standard Metals Co., of Chicago; big strikes on the Dall & Coulthard lands continue.

Benton.

Shipments of mine run ore to track for week of 7th totaled 54 cars, 4,230,000 lbs.; lead ore, 4 cars, 153 tons; pyrites, 210 tons. H. Lewis, field representative of the Eagle-Picher Lead Co., secured heavy tonnages for early delivery. The Wisconsin Zinc Co. being a large contributor. Fields Mining & Milling Co. of Chicago has entered into contract with Grasselli Chemical Co. for a period of years, and last week shipped 6 cars, 226 tons. The Vinegar Hill Co. took the lead in shipments last week with 13 cars to separators at Cuba, 4 from the Blackstone, 3 from the Martin, and 6 from the Kittoe, the last named having proved a large producer for the past 2 years. Benton Roasters, high grade to Collinsville, 38 tons; Wisconsin Zinc Co., high grade to Collinsville, 3 cars, 116 tons; to American Zinc Co., 5 cars, 197 tons. Grand View, Sally and Wilkinson each reported a car last week. All are new producers.

Galena.

Shipments from Black-Jack were 6 cars to Mineral Point last week, 250 tons. North Unity, Federal and Day Mining each sent 1 car to market. Galena Refining Co. failed to report. Wisconsin Zinc Roasters sent 2 cars to LaSalle, 72 tons; 1 car to Hillsboro, 40 tons.

WYOMING.

Greybull.

The Liberty Oil & Gas Co. is down 1000 ft. Realizing that much better time can be made with a heavier rig, Supt. C. E. Russell has gone to Seattle, the home office of the company, to purchase a Standard rig. The company proposes to drill several wells in the district. The Northwest Oil & Development Co. has let a contract for the sinking of another well east of the one that was brought in recently. Crall & Hyde are drilling on the Rogers' ranch. They had a fishing job for several days but are again at work. Edwards brothers have let a contract to sink a well on their recently acquired property on the south side of Greybull river. A new hole has been started on the property of the Greybull Oil & Development Co. south of Greybull river. A new contract has been drawn up and it is hoped that the trouble the company has been having is eliminated. A new hole has also been started at the Reynolds & Sypher property on Greybull river.

CANADA.

BRITISH COLUMBIA.**Nelson.**

Negotiations for the bonding of the Canadian Pacific group of claims in the Ymir district by John Arbuthnot of Victoria and New York associates have virtually been completed by Edward Peters of Nelson, one of the owners of the claims. The price is \$75,000. The group lies 4 miles from Ymir and near the Wilcox mine. It is a big low-grade gold proposition, on which surface work has exposed four veins from 4 to 30 ft. in width for a distance of about a mile. Assays show values to run from \$1.80 to \$14 in gold, and with silver values up to 10 ozs. Among those associated with Dr. Peters are George F. Motion, Dr. L. E. Borden, George H. Colwell, C. G. Peters and Robert Smillie of Nelson.

Sandon.

The Ivanhoe mill, built to replace the first plant destroyed by fire last year, will be completed within the next 2 weeks, and will commence what promises to be a long run on ores from the Surprise, now being developed at a vertical depth of 1200 ft. through No. 3 tunnel of Last Chance on the Cody Creek side of the mountain. The plant is being rebuilt under an agreement between W. H. Yawkey, of New York, owner of the Ivanhoe, and Alex Smith, manager and part owner of Surprise. The capacity is about 100 tons a day. Surprise ore will be brought from the mine over the Last Chance aerial tramway to the road bed of the abandoned Kaslo & Slocan narrow-gauge railroad below Cody. From there it will be hauled 2 miles to bins below the road bed and opposite the mill, and taken by aerial tram across the Carpenter Creek gulch to the mill bins. Little official information concerning mine conditions is obtainable, but there is no doubt that splendid reserves have been placed in sight by the deep development carried on persistently and quietly for so many years. The ore is said to contain good values in silver, lead and zinc and the mill is being equipped with flotation process and other modern improvements. The property has been steadily developed for 20 years under private ownership of Congressman Charles Kent, of California, and Alex Smith, who has had charge of operations during the entire period. The Ivanhoe has recently been reopened under lease, and the tramway is being put in shape to transport ore to the mill. The property was extensively developed by Yawkey and his father over 15 years ago, but has been idle for at least 10 years. The old mill was under lease to Keane & Cunningham for treatment of Lucky Jim ores when it was destroyed.

Greenwood.

Oscar Lachmund, general manager of the British Columbia Copper Co., has been unable to secure from either Coleman or Fernie sufficient coke to open up another furnace at the company's Greenwood smelter, where only one furnace is being operated. Shortage of labor at both Fernie and Coleman and a lack of demand for coal at the latter place are reasons given for the coke shortage. Fernie is said to need 500 more men to provide the coke needed by the Granby at Grand Forks, and the Consolidated at Trail. Granby is running seven furnaces, but may have to drop to six. Trail hopes to blow in two idle copper furnaces this week, but it is uncertain if it will have a sufficient supply of coke on hand to do so. At Coleman, the colliery has two seams, of which the upper is non-coking coal and the lower is coking coal. The lower can not advantageously be worked without the upper, so that when demand for coal falls off coke production is reduced. It is for this reason that the demand for coal as well as the labor supply is a factor in Coleman's coke output. Development work which has as its immediate purpose the blocking out of 5,000,000 tons of copper ore and as its secondary purpose the blocking out of a second 5,000,000 tons, is making good progress at the British Columbia Copper Co.'s Copper mountain properties, stated Mr. Lachmund. At Copper mountain, which is 13 miles from Princeton, the 2000-ft. crosscut tunnel the company is driving is in about 1200 ft., this distance having been driven since June 15. It

is proving conditions revealed by diamond drill explorations, which showed 5,000,000 tons of ore on this level. This crosscut, which when 2000 ft. have been driven will be extended in several directions, will give a maximum depth on the ore of 200 ft., the comparatively short distance between the apex and the floor of the tunnel providing for the glory hole operations the company intends to carry on when ore production begins.

ONTARIO.**Schumacher.**

The No. 1 vein at the Schumacher mine has been opened on the 100 level and drifted on for 150 ft. and it is expected that it will soon be encountered on the 200 level. Development is being pushed. From 300 to 350 ft. of crosscutting and drifting is being done per month. Last month 20% of the ore milled came from development. The new 2-compartment shaft being sunk near the railway line is down 68 ft. Sinking is being done at the rate of 25 ft. a week. The shaft is being put down midway between two veins, and will be continued to the 200 level, where crosscuts will be made to each, and it is thought that the desired level will be reached by Nov. 10. The compressor plant is limited to 15 machines and at present is working to capacity. Operations are being carried on at all levels. On the 1st level 3 machines are working in ore. Five Leyners are working, development being carried on a scale greater than at any time. The dump is being run through, but this will not last long at the rate of handling. Preparations are being made on surface for the coming of winter, in the way of laying pipe lines. The new machine shop has been completed and the machinery, which is being brought up from the Swastika, will arrive soon. Following the accident to the transformers during a severe electrical storm, the compressor has been run by steam. Three of the transformers will be ready in 10 days or so. The mill is handling 1000 tons a week. The heads are running \$5 and the production is being maintained at about \$20,000 per month.

Porcupine.

The winze at the Porcupine Crown is down to the 900 level and the vein looks promising on the 600. At a point below the vein has either narrowed or faulted. Further work will determine this. The finding of the vein on the 800 was expected. As yet not enough work has been done to prove it. The tailings dump from the former amalgamation mill is being run through, and is now about 60% gone. The 200-ton crusher ordered last spring has not been received as yet. The latter was promised for Sept. 1. The present crusher is of 100 tons capacity and has to be forced above capacity to supply the mill.

Cobalt.

Development underground at the Dome Lake is now satisfactory. On the 180 level up to 70 ft., in the stope on one vein, the vein faulted. The fault has been crossed through and stoping is now being done above it in good ore. There is a new shoot on No. 2 vein on the 180 level. The shoot has only been opened a short distance, but drifting is being done on it now. On the 300 level No. 2 stope has been lengthened to the south and west. The average width is from 10 to 15 ft. and the average value about \$30. No. 2 is the biggest stope of high-grade in the mine. East of the dike, on the 300, No. 1 stope is 150 ft. long. The ore runs \$6 with high-grade in places. On the 400 ore has been located east of the dike and drifting is in progress. Two faces are in ore. To the west drifting is being pushed rapidly on No. 1 and a large tonnage is being developed. The shaft is down 456 ft. and sinking is still in progress to the 500 level. Here a station will be cut and drifting done on the same vein system. At the mill foundations are completed and the plate floors are being moved and new elevators constructed. The water tank is up and the ore bin for the Hardinge ball mill started. The stamps will run from the same bin. Only the one for the Hardinge mill is being built now. The classifiers have already been installed and the Koering drum is complete. It is expected that the new mill will be ready to run by Oct. 20, treating 200 tons daily. The increased mill capacity will give the company a chance to treat a large amount of the \$4 ore above the 300 level. Of the latter grade there is a large tonnage, which has scarcely been touched.

World's Index of Current Literature

A Weekly Classified Index to Current Periodical and other Literature, Appearing the World Over Relative to Mining, Mining Engineering, Metallurgy and Related Industries, in Four Parts.

Part 1. *Geology*—(a) Geology; (b) Ore Genesis; (c) Mineralogy.

Nickel

Hammond, L. D.—*The Electrodeposition of Nickel*. [Tables and description showing the chemicals used in different electrolytes are given with the current used in deposition and all the information given is specific rather than general].—American Electrochem. Soc. Adv. Paper 12; p 201; pp 29; 35c.

Kelley, G. L.; Conant, J. B.—*The Use of Diphenyl Glyoxime as an Indicator in the Volumetric Determination of Nickel by Frevet's Method*. [Gives a description of procedure for the method and the use of the indicator].—Jnl. Ind. & Engg. Chem. Sept. 1916; p 804; pp 3; 60c.

Knight, Cyril W.—*Geological Relations of Sudbury Nickel Ores*. [Reviews the nature of the deposits and geology of the related formation. The whole is in the form of discussion].—E. & M. J. Sept. 23 1916; pp 1¾*; 25c.

Leonard, R. W.—*Nickel Refining in Canada*. [A general review of the industry].—Canadian Mg. Inst. Bull. Sept. 1916; p 758; pp 2; 50c.

Silver

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*Silver-Tin Mining in Bolivia*. [Old stope filling is being taken out, chloridized, leached and then concentrated for the tin residue].—E. & M. J. Sept. 23 1916; p 533; pp 3*; 25c.

— *Sullivan Mine, East Kootenay,*

B. C. [A description of mine operations and production, with an account of the geology of the formation and nature and occurrence of the ore bodies].—Canadian Mg. Jnl. Sept. 15 1916; p 444; pp 2¼; 35c.

Silver Milling, Metallurgy, Etc.

See Mill and Milling, Metallurgy, Chemistry, Assaying, Etc.

Zinc

Henderson, Charles W.—*New Mexico Metal Production in 1915*. [Abst. from a U. S. G. S. report. Zinc, lead and copper are considered].—Mg. & Oil Bull. Sept. 1916; p 227; pp 3*; 25c.

Karr, C. P.—*Report on a Series of Comparative Tests of Zinc-Bronze (88 Cu-10 Sn-2 Zn) Standard Test Bars*. [Deals entirely with physical tests and the results obtained].—American Inst. of Metals Adv. Paper 16; pp 12; 35c.

— *Sullivan Mine, East Kootenay, B. C.* [A description of mine operations and production, with an account of the geology of the formation and nature and occurrence of the ore bodies].—Canadian Mg. Jnl. Sept. 15 1916; p 444; pp 2¼; 35c.

Miscellaneous Metals and Ores

Browning, P. E.; Spencer, S. R.—*On the Separation of Caesium and Rubidium by the Fractional Crystallization of the Aluminum and Iron Alums and Its Application to the Extraction of These Elements from Their Mineral Sources*.—American Jnl. of Sci. Sept. 1916; p 2½; 35c.

Wells, Arthur E.—*Laboratory Investigations Concerning the Reduction of Barium Sulphate to Barium Sulphide*. [Published by permission of the Bureau of Mines. Details of methods used in the investigation are given, with results obtained].—Jnl. Ind. & Engg. Chem. Sept. 1916; p 770; pp 7½*; 60c.

(II) NON-METALS

(A) FUELS

Coal Fields and Mining

Crankshaw, H. M.—*Methods of Mining in the Anthracite Field*. [Details in description and drawings show the methods used in mining operations].—Coal Age Sept. 23 1916; p 490; pp 3½*; 20c.

Fay, Albert H.—*Production of Explosives in the United States*. [Also contains notes on coal mine accidents due to explosives and a list of permissible explosives, lamps and motors tested before May 1 1916].—U. S. Bureau of Mines Tech. Paper 159; pp 24; 15c.

McGrath, J. W.—*Newfoundland Coal Deposits*. [A review of the deposits now being held as reserves and those being operated].—Canadian Mg. Jnl. Sept. 15 1916; p 439; pp 2½; 35c.

Sampson, R. J.—*An Economical System of Mining*. [The system allows of complete extraction of the ground at a low cost and consists mostly of pillar drawing. A tenacious sandstone roof permits the running of wide entries].—Coal Age Sept. 23 1916; p 494; pp 2¼*; 20c.

— *Coal Handling on the Norfolk & Western Railway*. [A brief description of the coal handling facilities and methods used by this road].—Coal Age Sept. 23 1916; p 498; pp 1½; 20c.

— *The Use of Squibs Vs. Fuses*. [The results of a thorough study made by the British Government bringing out that in general squibs are the safest and best].—Coal Age Sept. 23 1916; p 501; pp 1½; 20c.

Coal Preparation, Marketing, Etc.

Davenport, Frank B.—*The History of a Successful Jig*. [Drawings and description are given].—Coal Age Sept. 23 1916; p 497; pp 1½*; 20c.

Holbrook, E. A.—*Dry Preparation of Bituminous Coal at Illinois Mines*. [The nature of the coal and the deposits are described. Drawings of tipples and plants are shown and a complete description of methods used in preparing coal is given].—Univ. Ill. Bull. 43; pp 133*.

— *Surface Plant at Brodsworth Main Colliery, England*. [Turbines using mixed pressure steam are used. Hoist, boilers, compressed air, etc., are described].—Colly Guard. Sept. 1 1916; p 401; pp 1½*; 35c.

(B) STRUCTURALS AND CERAMICS

Brick and Tile

Kelley, W. H.—*Fire Brick for the Lime Kiln*. [A talk on the uses and properties of different brick used in different plants].—National Lime Mfg. Bull. 21; pp 5; 25c.

Cement

Burhard, Ernest F.—*Potash as a By-Product in the Cement and Iron Industries*. [Abst. from the Manufacturer's Record. Consists of some details in a general discussion and review of the subject].—Chem. Eng. & Mfg. Sept. 1916; p 104; pp 4; 30c.

Findlay, D. C.—*Electrification of a Modern Cement Plant*. [A description of the Oregon Portland Cement Co.'s plant].—Jnl. of Elect. Power & Gas Sept. 16 1916; p 218; pp 2*; 35c.

Clays, Ceramics

Greaves-Walker, A. F.—*"Tight Bolt" Setting in Up-Draft Kilns*. [A method little used in this country, but which saves labor, produces more even burns and eliminates kiln markings].—B. & C. Rec. Sept. 19 1916; p 510; pp 2¼*; 35c.

Huac, A. J.—*Cost Accounting for the Clay Plant*. [A part of a series of articles on a complete accounting system].—B. & C. Rec. Sept. 19 1916; p 513; pp 1½*; 35c.

Concrete

Hull, Walter A.—*Investigation of Fire Resisting Materials Particularly as Related to Limestone Concrete*. [Describes the furnaces used and gives curves and description with respect to the results of the investigations].—National Lime Mfg. Bull. 20; pp 14*; 25c.

McMillan, Franklin R.—*Time Tests of Concrete*. [A paper read before the Engineers' Club of St. Louis. Curves and the results of tests are given].—Canadian Eng. Sept. 14 1916; p 211; pp 4¼*; Sept. 21 1916; p 231; pp 4*; 70c.

Emley, W. E.—*The Comparative Values of Different Kinds of Fuels for Lime Burning*. [Specific data and information are included in the description].—National Lime Mfg. Bull. 22; pp 6; 25c.

Lime

Hull, Walter A.—*Investigations of Fire Resisting Materials, Particularly as Related to Limestone Concrete*. [Describes the furnaces used and gives curves and description with respect to the results of the investigations].—National Lime Mfg. Bull. 20; pp 14*; 25c.

— *False Prophets in the Machinery Business for the Sake of False Profits*. [A talk on machinery and the lime manufacturing industry].—National Lime Mfg. Assn. Bull. 19; pp 4.

(C) OTHER NON-METALS

Acids

Harris, T. N.—*New Sulphuric Acid Plant*. The construction and method of manufacture used by the U. S. Steel Corporation at its plant at Donora, Pa.—*Met. & Chem. Engg.* Sept. 15 1916; p 313; pp 5¾*; 35c.

Phalen, W. C.—*Sulphur, Pyrite and Sulphuric Acid in 1915*. [A review of production and conditions, including some foreign countries].—*Min. Res. U. S. II*: 22; pp 16.

Asbestos

Dunstan, B.—*Queensland Mineral Deposits, Australia*. [A detailed description of nature of occurrence, production, prospects and methods of concentration of asbestos ores].—*Queen. Govt. Mg. Jnl.* Aug. 15 1916; p 372; pp 3½*; 35c.

—*Quebec Mining Industry—A Review for the First Half of 1916*. [Brief accounts of operations at various properties].—*Canadian Mg. Inst. Bull.* Sept. 1916; p 796; pp 4; 50c.

Potash

Burchard, Ernest F.—*Potash as a By-Product in the Cement and Iron Industries*. [Abst. from the Manufacturer's Record. Consists of some details in a general discussion and review of the subject].—*Chem. Eng. & Mfg.* Sept. 1916; p 104; pp 4; 30c.

Hicks, W. B.—*Simple Tests for Potash*. [In general the test consists of flame coloration peculiarities].—*American Fertilizer* Sept. 16 1916; p 30; pp 1¾; 25c.

Sulphur

Osann, B.—*Behavior of Sulphur in the Blast Furnace*. [The reduction is regarded as taking place in the semi-solid magma].—*Stahl & Eisen* 1916 No. 36; p 210; pp 5; 35c.

Phalen, W. C.—*Sulphur, Pyrite, and Sulphuric Acid in 1915*. [A review of production and conditions, including some foreign countries].—*Min. Res. U. S. II*: 22; pp 16.

—*Quebec Mining Industry—A Review for the First Half of 1916*. [Brief accounts of operations at various properties].—*Canadian Mg. Inst. Bull.* Sept. 1916; p 796; pp 4; 50c.

Miscellaneous Non-Metals

Phalen, W. C.—*Salt, Bromine and Calcium Chloride in 1915*. [Deals with production only].—*Min. Res. U. S. II*: 20; pp 12.

Robinson, Heath M.—*The Ozokerite Field in Central Utah*. [Abst. from a U. S. G. S. bulletin. Genesis, properties, production, concentration, etc., are considered].—*Mg. World* Sept. 16 1916; p 497; pp 1¾*; 10c.

III. TECHNOLOGY

MINES AND MINING

Ore Reserves

Key, A. Cooper.—*The Rand's Ore Reserves*. [Description and tabulated information and data are given].—*E. & M. J.* Sept. 23 1916; p 557; pp 1¾; 25c.

McGrath, J. W.—*Newfoundland Coal Deposits*. [A review of the deposits now being held as reserves and those being operated].—*Canadian Mg. Jnl.* Sept. 15 1916; p 439; pp 2½; 35c.

Explosives and Blasting

Fay, Albert H.—*Production of Explosives in the United States*. [Also contains notes on coal mine accidents due to explosives and a list of permissible explosives, lamps and motors tested before May 1 1916].—*U. S. Bureau of Mines Tech. Paper* 159; pp 24; 15c.

—*The Use of Squibs Vs. Fuses*. [The results of a thorough study made by the British Government, bringing out that in general squibs are the safest and best].—*Coal Age* Sept. 23 1916; p 501; pp 1½; 20c.

Pumps and Pumping

Alderson, G. F.—*A Reservoir and Pumphouse*. [Describes the construction of the installation and itemization of costs].—*E. & M. J.* Sept. 23 1916; p 547; pp 1¾*; 25c.

Scott, W. A.—*Leadville Pumping and Drainage Projects*. [Descriptions are given of methods used and plants at various places in the district which use different kinds of power, styles of pumps and methods of operation].—*Mg. World* Sept. 23 1916; p 533; pp 3¾*; 10c.

Transport

Clapp, W. B.—*Motor Truck Development and Use in Southern California*. [A very complete table is given showing the cost of operating gasoline motor trucks at various mileages].—*Mg. & Oil Bull.* Sept. 1916; p 222; pp 6; 25c.

—*Antimony Ore in Southern Rhodesia*. [Types of occurrences and methods for calculating shipments and cost of the same are explained].—*S. Afr. Mg. Jnl.* Aug. 19 1916; p 465; pp 1; 35c.

—*Coal Handling on the Norfolk & Western Railway*. [A brief description of the coal handling facilities and methods used by this road].—*Coal Age* Sept. 23 1916; p 498; pp 1½; 20c.

Production

Browne, P. W.—*Mineral Resources of Newfoundland*. [A review of the possibilities in operating the iron ore and copper deposits of the province. The past production of mines is given].—*Canadian Mg. Jnl.* Sept. 15 1916; p 437; pp 1¾; 35c.

Fay, Albert H.—*Production of Explosives in the United States*. [Also contains notes on coal mine accidents due to explosives and a list of permissible explosives, lamps and motors tested before May 1 1916].—*U. S. Bureau of Mines Tech. Paper* 159; pp 24; 15c.

Henderson, Charles W.—*New Mexico Metal Production in 1915*. [Abst. from a U. S. G. S. report. Zinc, lead and copper are considered].—*Mg. & Oil Bull.* Sept. 1916; p 227; pp 3*; 25c.

Phalen, W. C.—*Sulphur, Pyrite and Sulphuric Acid in 1915*. [A review of production and conditions, including some foreign countries].—*Min. Res. U. S. II*: 22; pp 16.

Schaller, Waldemar T.—*Mica in 1915*. [Gives prices, imports, exports, uses, production, nature and place of occurrence, foreign markets and general conditions of the industry in U. S.].—*Min. Res. U. S. II*: 21; pp 14.

Sieenthal, C. E.—*Lead in 1915*. [On the production and market conditions in United States and briefs on several foreign countries].—*Min. Res. U. S. I*: 9; pp 19.

—*Kleinfontein, South Africa*. [Deals with the future of the district and reviews the production, financial information and general mine operations in the

district].—*S. Afr. Mg. Jnl.* Aug. 12 1916; p 440; pp 1¾*; 35c.

—*Sullivan Mine, East Kootenay, B. C.* [A description of mine operations and production, with an account of the geology of the formation and nature and occurrence of the ore bodies].—*Canadian Mg. Jnl.* Sept. 15 1916; p 444; pp 2¾; 35c.

Mining Costs

Jennings, Hennen.—*Dredging in Montana*. [From a U. S. G. S. Bulletin, giving the costs of operation and construction of dredges used.—*M. & S. P.* Sept. 23 1916; p 465; pp 2½*; 20c.

Lewis, Robert S.—*Amortization and Depreciation*. Deals with methods for computing the same and states that omission of the same in computing costs is a great mistake, which is often made].—*M. & S. P.* Sept. 23 1916; p 456; pp 3*; 20c.

—*Gold Mining in War Time*. [A review of the conditions, prices and taxes in West Australia].—*Monthly Jnl. Chamber of Mines West Aust.* June 30 1916; p 108; pp 4½; 35c.

CHEMISTRY AND ASSAYING

Chemistry

Kelley, G. L.; Conant, J. B.—*The Use of Diphenyl Glyoxime as an Indicator in the Volumetric Determination of Nickel by Frevvert's Method*. [Gives a description of procedure for the method and the use of the indicator].—*Jnl. Ind. & Engg. Chem.* Sept. 1916; p 804; pp 3; 60c.

Schroeder, J.—*The Solubility of Leucite in Sulphurous Acid*. [Details of the chemistry and methods applied thereto].—*Jnl. Ind. & Engg. Chem.* Sept. 1916; p 779; pp 1; 60c.

Wells, Arthur E.—*Laboratory Investigations Concerning the Reduction of Barium Sulphate to Barium Sulphide*. [Published by permission of the Bureau of Mines. Details of methods used in the investigation are given, with results obtained].—*Jnl. Ind. & Engg. Chem.* Sept. 1916; p 770; pp 7½*; 60c.

Analysis

Kelley, G. L.; Conant, J. B.—*The Use of Diphenyl Glyoxime as an Indicator in the Volumetric Determination of Nickel by Frevvert's Method*. [Gives a description of procedure for the method and the use of the indicator].—*Jnl. Ind. & Engg. Chem.* Sept. 1916; p 804; pp 3; 60c.

Leaming, T. H.; Schlundt, Herman; Underwood, Julius.—*Comparison of the Ionization Currents Due to Equal Quantities of Radium Emanation in Different Types of Electroscopes*. [A method by which small quantities of radium may be determined].—*American Electrochem. Soc. Adv. Paper* 2; p 13; pp 14; 35c.

Refractories

Kelley, W. H.—*Fire Brick for the Lime Kiln*. [A talk on the uses and properties of different brick used in different plants].—*National Lime Mfg. Bull.* 21; pp 5; 25c.

METALLURGY

Electrometallurgy

Crowley, John A.—*The Gronwall-Dixon Electric Furnace*. [A paper read before the American Foundrymen's Assn. Deals with the construction of the furnace, its operation and gives drawing and detailed costs of producing steel with the same].—*I. Tr. Rev.* Sept. 21 1916; p 571; pp 2½*; 25c.

Fischer, Sigfried, Jr.—*Contributions to the Knowledge of the Electrolysis*

Aqueous Solutions of Vanadium Salts. [Gives the results of previous investigations showing the behavior of vanadium and its salts under various conditions, specially in solution as an electrolyte].—American Electrochem. Soc. Adv. Paper 9; p 119; pp 45*; 35c.

Hammond, L. D.—*The Electrodeposition of Nickel.* [Tables and description showing the chemicals used in different electrolytes are given with the current used in deposition and all the information given is specific, rather than general].—American Electrochem. Soc. Adv. Paper 12; p 201; pp 29; 35c.

—*Electric Alloy Steels Made on Tonnage Basis.* [A detailed description of the plant equipment and operation is given].—Iron Age Sept. 14 1916; p 571; pp 3½*; 30c.

Hydro-Metallurgy

Fischer, Sigfried, Jr.—*Contributions to the Knowledge of the Electrolysis Aqueous Solutions of Vanadium Salts.* [Gives the results of previous investigations showing the behavior of vanadium and its salts under various conditions, specially in solution as an electrolyte].—American Electrochem. Soc. Adv. Paper 9; p 119; pp 45*; 35c.

Hammond, L. D.—*The Electrodeposition of Nickel.* [Tables and description showing the chemicals used in different electrolytes are given with the current used in deposition, and all the information given is specific rather than general].—American Electrochem. Soc. Adv. Paper 12; p 201; pp 29; 35c.

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*Silver-Tin Mining in Bolivia.* [Old stope filling is being taken out, chloridized, leached and then concentrated for the tin residue].—E. & M. J. Sept. 23 1916; p 533; pp 3*; 25c.

POWER AND MACHINERY

Electricity

Leaming, T. H.; Schlundt, Herman; Underwood, Julius.—*Comparison of the Ionization Currents Due to Equal Quantities of Radium Emanation in Different Types of Electroscopes.* [A method by which small quantities of radium may be determined].—American Electrochem. Soc. Adv. Paper 2; p 13; pp 14; 35c.

Scott, W. A.—*Leadville Pumping and Drainage Projects.* [Descriptions are given of methods used and plants at various places in the district which use different kinds of power, styles of pumps and methods of operation].—Mg. World Sept. 23 1916; p 533; pp 3½*; 10c.

Compressed Air

Burch, H. K.—*The Inspiration Mine Plant.* [Abst. from a paper read before the A. I. M. E. Describes the equipment and methods used for handling the ore from the mine, both underground and on the surface].—E. & M. J. Sept. 23 1916; p 537; pp 5½*; 25c.

Miscellaneous Power and Machinery

—*Purchase and Inspection of Leather Belting.* [From the American Machinist, being a general discussion of the subject].—E. & M. J. Sept. 23 1916; p 549; pp 1½; 25c.

of the installation and itemization of costs].—E. & M. J. Sept. 23 1916; p 547; pp 1½*; 25c.

Clapp, W. B.—*Motor Truck Development and Use in Southern California.* [A very complete table is given showing the cost of operating gasoline motor trucks at various mileages].—Mg. & Oil Bull. Sept. 1916; p 222; pp 6; 25c.

Huac, A. J.—*Cost Accounting for the Clay Plant.* [A part of a series of articles on a complete accounting system].—B. & C. Rec. Sept. 19 1916; p 513; pp 1½*; 35c.

—*Antimony Ore in Southern Rhodesia.* [Types of occurrences and methods for calculating shipments and cost of the same are explained].—S. Afr. Mg. Jnl. Aug. 19 1916; p 465; pp 1; 35c.

Testing

Corse, W. M.; Comstock, G. F.—*Some Copper-Aluminum-Iron Alloys.* [Deals with the physical properties and nature of the alloy. A metallographic review of the alloys and the results of physical tests are given].—American Inst. of Metals Adv. Paper 14; pp 16*; 35c.

Edmonds, H. R.—*Some Notes on the Effect of Lead Salts and of Varying Degree of Alkalinity on the Solvent Power of Cyanide Solution for Gold.* [Gives the results of some tests made].—Monthly Jnl. Chamber of Mines West Aust. June 30 1916; p 108; pp 4½; 35c.

Fischer, Sigfried, Jr.—*Contributions to the Knowledge of the Electrolysis Aqueous Solutions of Vanadium Salts.* [Gives the results of previous investigations, showing the behavior of vanadium and its salts under various conditions, specially in solution as an electrolyte].—American Electrochem. Soc. Adv. Paper 9; p 119; pp 45*; 35c.

Karr, C. P.—*Report on a Series of Comparative Tests of Zinc-Bronze (88 Cu-10 Sn-2 Zn) Standard Test Bars.* [Deals entirely with physical tests and the results obtained].—American Inst. of Metals Adv. Paper 16; pp 12; 35c.

McMillan, Frank R.—*Time Tests of Concrete.* [A paper read before the Engineers' Club of St. Louis. Curves of results are reproduced and details of results given in the description].—Canadian Eng. Sept. 21 1916; p 231; pp 4*; 35c.

Price, William B.; Davidson, Philip.—*Physical Tests on Common High Brass Taken Parallel and at Right Angles to the Direction of Rolling.* [The results and nature of the physical tests under varying conditions with a metallographic review is given].—American Inst. of Metals Adv. Paper 12; pp 32*; 35c.

Metallography

Comstock, George F.—*The Presence of Alumina in Steel.* [A paper read before the American Foundrymen's Assn. This paper points out that alumina may be distinguished from non-metallic inclusions and shows how it may be distinguished].—I. Tr. Rev. Sept. 21 1916; p 563; pp 5*; 25c. Iron Age Sept. 19; p 582; pp 2¾*; 30c.

Corse, W. M.; Comstock, G. F.—*Some Copper-Aluminum-Iron Alloys.* [Deals with the physical properties and nature of the alloy. A metallographic review of the alloys and the results of physical tests are given].—American Inst. of Metals Adv. Paper 14; pp 16*; 35c.

Price, William B.; Davidson, Philip.—*Physical Tests on Common High Brass Taken Parallel and at Right Angles to*

the Direction of Rolling. [The results and nature of the physical tests under varying conditions with a metallographic review is given].—American Inst. of Metals Adv. Paper 12; pp 32*; 35c.

Touceda, Enrique.—*Normal Fracture of Good Malleable Iron.* [A paper read before the American Foundrymen's Assn. on the effect of haphazard fractures and the burning out of surface carbon, showing an erroneous theory regarding the strength].—Iron Age Sept. 14 1916; p 576; pp 2*; 30c.

Law, Legislation, Taxation

—*Gold Mining in War Time.* [A review of the conditions, prices and taxes in West Australia].—Monthly Jnl. Chamber of Mines West Aust. June 30 1916; p 108; pp 4½; 35c.

History

Davenport, Frank B.—*The History of a Successful Jig.* [Drawings and description are given].—Coal Age Sept. 23, 1916; p 497; pp 1½*; 20c.

Elmore A. Stanley.—*The Invention, Development and Introduction of the Flotation Process.* [A general historical account of the process carrying the method to a point where it was practically introduced].—M. & S. P. Sept. 23 1916; p 449; pp 6½; 20c.

Societies

—*American Institute of Metals.*—I. Tr. Rev. Sept. 21 1916; p 588; pp 3*; 25c.

—*American Mining Congress, Nineteenth Annual Meeting.*—Mg. World Sept. 23 1916; p 539; pp 2; 10c.

—*Arizona Meeting of A. I. M. E.* [An account of the society's trips].—E. & M. J. Sept. 23 1916; p 558; pp 1½; 25c.

—*Cleveland Meeting of Allied Foundry Organizations.*—I. Tr. Rev. Sept. 21 1916; p 579; pp 9½*; 25c.

—*Meeting of the American Chemical Society and the Second National Exposition of Chemical Industries.*—Jnl. Ind. & Engg. Chem. Sept. 1916; p 856; pp 2; 60c.

Financial

Huac, A. J.—*The Value of a Clay Deposit.* [Formulas are given and their application explained and include all formulas needed in figuring the value of a deposit which was formerly done mostly from experience].—B. & C. Rec. Sept. 19 1916; p 499; pp 2½*; 35c.

Lewis, Robert S.—*Amortization and Depreciation.* [Deals with methods for computing the same and states that omission of the same in computing costs is a great mistake which is often made].—M. & S. P. Sept. 23 1916; p 456; pp 3*; 20c.

—*Kleinfontein, South Africa.* [Deals with the future of the district and reviews the production, financial information and general mine operations in the district].—S. Afr. Mg. Jnl. Aug. 12 1916; p 440; pp 1½*; 35c.

General Miscellany

Alderson, G. F.—*A Reservoir and Pumphouse.* [Describes the construction of the installation and itemization of costs].—E. & M. J. Sept. 23 1916; p 547; pp 1½*; 25c.

Corless, C. P.—*Widespread and Increased Intelligence, the Surest Remedy for Industrial Ills.* [An essay on the subject].—Canadian Mg. Inst. Bull. Sept. 1916; p 764; pp 9; 50c.

IV. MISCELLANEOUS

Miscellaneous Costs

Alderson, G. F.—*A Reservoir and Pumphouse.* [Describes the construction

Ore and Metal Markets; Prices-Current

New York, Oct. 12, 1916.

Silver.—Quotations for silver per fine ounce at New York and per standard ounce at London for the week ended Oct. 11 were as follows:

Difference in domestic and foreign prices explained by the fact that the New York quotations are per fine ounce; the London per standard ounce 8.925 fine.

Copper.—Domestic buying of copper continued with unabated energy last week, transactions amounting to about 65,000,000 lbs. Even the outbreak of submarine activities on this side of the Atlantic failed to disturb the copper situation. Buying continued as though there were no possibility of another Lusitania incident and the results that would follow such a disaster. Copper is so strongly entrenched that incidents that would severely affect other metals fail to create the slightest ripple of a disturbance in the red metal. Foreign buying appears to be about over. The English negotiations for 200,000,000 lbs. additional have come to naught. Some miscellaneous foreign business is steadily coming to hand, but the satiating of domestic requirements is the dominant occupation of producers. Practically all of the large domestic consumers have covered their needs over the first half of next year. There still remain a considerable number of users who have only protected first quarter needs and these latter interests are steadily coming into the market for supplies for the second quarter. On Thursday of last week the business taken by one producer amounted to 30,000,000 lbs.

Little copper remains unsold in the hands of producers for delivery this year. Investigation shows that all of the prominent producers have disposed of every pound of copper that they will produce this year. Some of the producers have laid aside a small tonnage with which to meet the wants of regular customers in case of a sudden shortage, but any buyer seeking metal for delivery this year would have to go to dealers for it. Spot electrolytic is quoted at a range from 28¼ to 29½ cts. For November delivery sales have been made at 28¼ cts., while for December delivery business has been done at 28¼@28½ cts. These quotations are on regular terms, while cash prices are about a half cent lower. Prime lake copper for prompt October and November delivery is available at 28½ cts. cash, while for December delivery sellers asked 27¼ cts. Spot casting copper sold up to 27¼ cts., with some business done at 27½ cts. Casting copper for November delivery is quoted at 27¼ cts. Ordinary casting copper is quoted a half to three-quarters of a cent lower.

Producers reported heavy bookings for the first half of next year. Consumers who have not covered are heeding the advice of important factors and are putting their orders in before there is a shortage for the first six months of 1917. At the present rate of bookings little copper for first half 1917 delivery will be available for sale by the end of

November. Sales of electrolytic for the first quarter are being done at 27½ cts. and for the second quarter at 27 cts.

The market is now shaping for an effort on the part of certain large dealers to depress prices in order to accumulate supplies. This is usually accomplished by forced sales and has in the past been effective in lowering producers' prices. A different result may now develop. Producers assured buyers of the recent past that the market would not go lower in any event and with their extensive business in hand there is no doubt that dealers will find an unusually strong market to combat in their efforts to secure stocks of metal. Second hands have confined their selling operations to nearby deliveries and as soon as they begin offering for the first half then it will be known that their movement to depress first hand sellers' prices has been started.

The London market has continued to move towards higher ground. Last week electrolytic advanced £2 to £142, while gains of £2 were also made in standard copper, with further advances in standard this week.

There have been no startling developments in connection with exports of copper. September exports, according to preliminary returns, not including Gulf ports of Pacific coast shipments, totaled 29,803 tons, so that the detailed statistics will show shipments of slightly over 1000 tons a day last month. Since the first of October exports have aggregated 5225 tons. It is expected that exports of copper in the first three months of next year will pass 40,000 tons a month and that by midsummer of next year exports of 50,000 tons a month would not be surprising.

Tin.—Great strength developed in tin last week and has continued this week. The detailed statistics were especially favorable, showing declines in the total visible supply and much smaller shipments from the Straits. This helped to strengthen the spot position, while higher limits from the east brought futures up to April within three-quarters of a cent of spot metal.

Spot Straits tin closed last week at 40 cts. On Monday of this week there were no sellers, but many buyers. Sellers refused to be drawn into making quotations. Buyers offered 43 cts. for spot Straits and 42 cts. for spot Banka, without forcing sellers to recede from their determination not to quote. The tin market verged on the border of a panic. On Monday there was absolutely no future business doing at all, while last week sales of about 700 tons were noted on which shipments run up to June of next year. Limits for December, January, February and March shipments held around 39¾@40 cts.

London and Singapore pursued a fairly even course, the upward movement being more pronounced in the east than at London. The Singapore market advanced to £181 10s, while Straits tin at London went up to £178 2s 6d. Standard tin advanced to £178 for spot and £178 10s for futures.

Quotations for tin per pound at New York and per ton at London and Singapore for the week ended Oct. 11 were as follows:

Lead.—Business fell off last week, due to the fact that domestic and foreign consumers had covered nearby requirements and were disposed to wait awhile before protecting needs over November and December in hopes of an easier market. Prominent factors in this metal declare that prospects for lower prices this year on lead are not very bright. They point out that Canada will be a large consumer for many months to come. Munition contracts that were placed in the Dominion were tremendous in size, as purchases of lead for October delivery alone to Canada amounted to over 10,000 tons. Russia and Japan are also in need of lead and must re-enter this market at a very early date. Producers are sold out for October and some of the independents have already sold out their first half November output. Thus the situation in lead is very strong, and while resellers may shade spot metal to the extent of \$1 a ton, the future situation is regarded as making higher prices certain. Dealers quote spot lead at 7.05 cts. New York and 6.85 cts. St. Louis. For November delivery outside sellers quote 7.05 cts. New York and for December delivery 7 cts. New York. The

London market has been receding. Last week spot moved off £1 5s to £30 15s and futures £1 to £29 10s.

Quotations for lead per pound at New York and per ton at London for the week ended Oct. 11 were as follows:

Lead Ore.—Lead ore showed a marked increase in production in the Missouri-Kansas-Oklahoma district last week, being no less than 1,000,000 lbs. greater than the week previous. Prices were firm at \$75, with choice ores bringing \$80. Production for the week totaled 2,160,690 lbs. of a value of \$67,990. The total for the year is 79,957,797 lbs. of a value of \$3,311,011.

Zinc Ore.—In the Missouri-Kansas-Oklahoma district last week the market was considerably stronger, low-grade ore jumping from \$5 to \$10, while the top was established at \$67.50, \$2.50 higher than the week previous. Production during the week totaled 13,913,350 lbs., making the total for the year 506,170,170 lbs., with values of \$407,086 and \$21,611,526 respectively.

Calamine.—Calamine was rather weak at \$37.

Spelter.—A very sizable business has been done in spelter, the demand only being interrupted by the commencement of submarine operations off our coast. This stoppage in business is thought to be only temporary, as no adequate reason can be put forth why speculative buying which had such zest last week should suddenly halt. Prices receded this week, but the upward movement was so sharp last week the current quotations are quite high. Spot moved up to 10¾ cts. New York and 10¾ cts. St. Louis, and at this writing is holding at 10 cts. New York and 9¾ cts. St. Louis. Prime western for the fourth quarter advanced to 10 cts. St. Louis and first quarter to 9¾ cts. St. Louis, but the reaction early this week carried fourth quarter down to 9¾ cts. St.

Louis and first quarter to 9½ cts. St. Louis. Brass special held at 10¼@11 cts. St. Louis for prompt delivery.

The London market has moved up steadily, going up £2 10s in spot and £3 10s in futures last week, with further advances of £2 10s in spot and futures at the opening this week.

Quotations for spelter per pound at New York and per ton at London for the week ended Oct. 11 were as follows:

MISCELLANEOUS METALS.

Quicksilver.—Scarcity of supplies and an active demand coming from domestic users caused quicksilver to advance to \$80 a flask, an advance of \$3 a flask since our last report. Sellers have been scouring the market for a few flasks, but in many instances failed to secure metal. Further advances are anticipated. Quite a little export business has been done in the past 2 months, against which supplies were not increased, thus bringing about the present shortage.

Antimony.—A better foreign demand is noted in antimony, while domestic inquiry appears to have improved. Italy and Canada have been in the market, the latter for quite a large amount. Prices moved up slightly on the prospect of more business, but the surplus holdings here have prevented any decided advance. Spot moved up to 11@11¼ cts. and business at 11½ cts., duty paid, has been done.

Aluminum.—An active demand for spot virgin ingots has been noted in the past few days, with the market inclined towards higher prices. Sellers have already advanced to 65@67 cts. for spot virgin metal. There is little business moving in remelted ingots, with prices unchanged at 59@60 cts. for No. 1 remelted and 47@48 cts. for No. 12 alloy. Large export shipments made by the leading interest have caused a shortage in nearby metal. For 1917 most of the business has been closed, consumers' contracts being renewed on a basis of 35 cts. f. o. b. smelter for No. 1 virgin ingots. There is an active demand for aluminum sheets for early delivery, prompt being sold at an average price of 90 cts., while contracts for next year have been renewed by the leading interest at 40 cts. base.

Tungsten.—There has been little change in the situation in tungsten ore. Demand continues light, while the supply is plentiful. Sellers continue to quote \$15 a unit delivered New York. This price compares with \$90 a unit paid early in the year.

Platinum.—Prices are repeated by refiners, with a fair demand. Soft platinum is quoted at \$90 an ounce and hard at \$96 an ounce.

Pig Iron.—Tremendous foreign buying of steel-making irons has featured the pig iron market recently, with prices advancing sharply. England took 200,000 tons basic from southern furnaces and 60,000 tons low phosphorus iron from Pennsylvania makers last week. Domestic demand for basic has also been large, sales totaling 75,000 tons. Basic has advanced to \$20.50 valley and bessemer to \$23.50 valley.

Foundry grades have also advanced 50 cts. to \$1 a ton, with buying more general. The situation in pig iron has improved wonderfully and startling price advances, such as characterized the steel market about a year ago, are looked for. Bessemer iron at \$25 and basic at \$23 are predicted by the end of October.

Ferromanganese.—With the improvement in pig iron higher prices on ferromanganese are expected, but as yet the market holds at \$164 seaboard for English make and \$165 furnace for domestic. Spiegeleisen, 20%, is quoted at \$45@50 furnace for spot or contract, while ferrosilicon is quoted at \$83@85 Pittsburgh for 50%.

WOLF TONGUE MINING CO.'S MILL, NEDERLAND, COLO.

Concentrating Tungsten Ores, Boulder County, Colorado

W. A. SCOTT.

In passing briefly over the tungsten producing interests of Boulder county, Colorado, no attempt will be made to discuss market conditions, nor make predictions as to future demands and consequent output of that metal. The best informed men of that locality, including producers and buyers, are not making calculations extending far into the future, concerning demands and prices. That many companies and individuals are well prepared to mine ore and turn out marketable concentrates, is everywhere evident. Nearly all seem to concur in the effort that is being made to influence action by Congress to fix an import duty on tungsten ores and tungstic acid, to protect American producers against the products of foreign mines, which are operated at much lower cost, especially as to labor. While some large foreign sources of supply are now cut off from our markets by the exigencies of war, it is realized that, with the probable cessation of hostilities soon, American tungsten production may be further depressed and curtailed by the importation of cheaper foreign ores, by which prices will be governed.

When, in the winter of 1915-16, demands became great and prices advanced, it was demonstrated that tungsten miners of the western states were quick to respond to this demand, their production for the first 6 months of 1916 having amounted to 3290 tons of 60% product, sub-divided as follows: Colorado, 1505

tons; California, 984 tons; Nevada, 461 tons; and 165 tons were produced by Alaska, Idaho, Utah, and other states. The imports for that period amounted to 1824 tons. This leads to the belief that the mines of this country are capable of producing tungsten sufficient to supply any domestic demands that may exist. Evidently, the element of uncertainty as to future prices is the foreign supply. A reasonable import duty probably would tend to steady the market, and keep the mines in this country in operation. It is surely of interest to both consumers and producers to avoid, if possible, radical fluctuations.

The Wolf Tongue Property.

The writer's main purpose is to report as accurately as he can some of the facts pertaining to milling methods and mill equipment observed in several of the tungsten concentrating plants. The first one visited was that of the Wolf Tongue Mining Co., situated at Nederland. This company's mineral holdings comprise 500 acres lying 2 miles north of that town. All of the 50 tons of ore per day being milled is taken from the company's mines, one-half being produced by the company direct, and one-half by lessees. The ore consists of ferberite, averaging about 7% WO_3 , the gangue being mostly silica and talc. The ore is first crushed to $\frac{1}{4}$ -in. size in a Blake jaw-crusher and a set of rolls. This product, after a 10% sample is cut out,

is passed to two Richards pulsator jigs, operating in series, with a dewatering box between the two units. Each unit is provided with separate pulsator valves and automatic gates for discharging coarse concentrates that accumulate above the screen and a hutch gate for discharging the fine concentrates that settle down through the screen. The coarse product ranges from $\frac{1}{2}$ to $\frac{1}{4}$ -in., and 10 mesh; the screen which holds it is 6 mesh, having 0.113-in. openings. The two products made on jig No. 1 consist of coarse concentrates running 63 to 57% WO_3 , and fine hutch concentrates running 60%; the product of jig No. 2, coarse con-

lic classifier; the overflow from the classifier is passed over Card and Wilfley slime tables, on which are made first-grade and second-grade concentrates, running 60 and 20% respectively. A third cut from the tables is returned to the ball mill circulation. The table tailings are retreated over Monell slimers, on which 40% tungsten concentrates are made, all tailings from Monell slimers passing over canvas plates. Now, the underflow, or heavier slimes, from the hydraulic classifier go to a Bunker Hill 30-mesh revolving screen; the plus 30-mesh is retreated over Card tables, the minus 30 goes to a Bunker Hill 50-mesh screen; the plus 50-

INTERIOR OF RARE METAL ORE CO.'S MILL, ROLLINSVILLE, COLO.

centrates, runs 20 to 30%. The Richards pulsator jig, made by Denver Engineering Works, has a pulsion stroke, upward, not accompanied by any counter suction. In this installation the total screen area of both jig units is only 2 sq. ft., and the two jigs in series treat 45 tons in 24 hours. The jig tailings are divided into two streams; one part is recrushed in two 5-stamp batteries, having 20-mesh screens, and the other part is reground in a Marcy ball mill, the latter reducing to 65 mesh. The stamps and ball mill are being run on the same material to ascertain comparative results. The pulp in each case is passed to a Richards hydrau-

mesh slime to a Card table, the minus 50 to a 100-mesh screen, and thence over slime tables and canvas plates. All Card tables yield a first-grade running 60% tungsten; a second-grade of 20%, the middlings being reground. The tailings from Card slimers is pumped to the canvas plates. The final tailings that go to the waste dump are from the latter plates. The "rag plant" contains 7600 sq. ft. of canvas plate. These plates are 3-decked, to economize room. The clean concentrates, comprising jig, table, slimer, and canvas products, are stove-dried, sacked and shipped.

The Wolf Tongue property is under the manage-

ment of William Loach, with C. A. De Witt, mill superintendent, and Wm. Todd, mine superintendent. The mines are opened through 10 shafts. The 25 sets of leasers on the property pay a royalty of 25%, the company furnishing all supplies and power for drills and hoists. There are about 150 men employed.

The Vasco Property.

The mill of Vasco Mining Co., situated at Tungsten, or Stevens camp, is being operated on 80 tons of tungsten ore per day. This plant was built and equipped by Hendrie & Balthoff Mfg. & Supply Co., Denver, and is doing efficient work. The Vasco oper-

RICHARDS PULSATOR JIG IN DUNCAN MILL.

ations are under the general superintendency of John Connors; Thos. McGrath and W. W. Waldron are mill and mine superintendent, respectively.

The larger tonnage of ore milled is taken from the 450-ft. crosscut, the portal of which is close to the mill. It intersects one principal vein in granite; and mining operations are going on both above and below this crosscut. Ore is dumped from mine cars into mill bins, and is thence elevated to the coarse crushing department, in which there is a Sampson 1½-in. crusher and a Universal ¾-in. The resultant product is reduced to ¾-in. by McFarlane rolls, and this is elevated to the fine ore bins, and from these it passes through three sets of trommels. The first set oversize, which is plus 3 mesh, is returned to the rolls for regrinding. The undersize of first to second trommel, or 10-mesh and the oversize from same, pass to Hurley 3-compartment jigs of different screen sizes. The third trommel undersize, or 14 mesh, is run through

Bunker Hill screens, by which it is classified for table concentration. About 50% of the entire mill recovery is made on these jigs. The jig tailings are sent to the waste dump, except as to certain grades of ore, wherein they are reground. The jig middlings, after being reground in a ball mill of Denver Engineering Works make, are reconcentrated over Card tables. The oversize from the Bunker Hill classifiers passes to tables, and the finer, or 100-mesh product to Callow tanks. The tank settlings are reconcentrated on Card slime tables, the overflow from tank being passed over canvas plates. When the jig tailings are reground in the ball mill, the pulp is first classified in an Akins machine, and thence to Bunker Hill cone classifier for table and canvas plate finishing. In this mill work, the jig product runs 50% WO₃, the table concentrates running 40 to 45%. The two crushers and one set of rolls operate dry, the wet pulverizing beginning with

RICHARDS PULSATOR JIGS IN TANDEM.

the McFarlane rolls. John McKenna, Boulder, is general manager of the Vasco Mining Co.

Tungsten Production Co.

J. G. Clark is manager of Boulder Tungsten Production Co., the mines and mill being at Stevens camp, on South Boulder creek. Principal mine operations are conducted through a 100-ft. crosscut, intersecting four veins of tungsten ore in granite, in which there are also dikes of porphyry and veins of quartz. There is about 1000 ft. of lateral development from the crosscut haulage level, tracks from that level leading to the crusher at the head of the mill. The milling plant, built and equipped by Colorado Iron Works, involves standard coarse and fine crushing, and concentration over jigs and tables.

Degge-Clark Operations.

Degge-Clark Tungsten Mining & Milling Co. is mining and milling 25 tons per day of ore running 7% tungstic acid, the mill concentrates carrying 50 to 60%. This company's highest grade ore is received from its Beaver creek properties, 15 miles southwest

from the mill, and is hauled thereto in auto trucks. The Beaver creek group contains a series of about 20 veins in porphyry, the development being through shafts and tunnels. Some of this ore assayed as high as 71%. The mill is a Colorado Iron Works plant, containing crusher, two sets of rolls, ball mill, jigs, tables, and canvas plates.

Duncan Mill.

John T. Duncan owns and operates the Black Prince tungsten mill, situated in Boulder canyon. It was designed by Geo. S. Love, and was constructed by Denver Quartz Mill & Crusher Co. It has a capacity of 25 tons per day, and this is to be increased to 75 tons. The equipment consists of that company's 8 by 12 steel crusher, its No. 2 ore feeder, the Denver Quartz mill pulverizer, with second unit being installed; a Richards' pulsator single jig, Isbell concentrators, and a Colorado Iron Works' diaphragm pump. The crusher oversize is recrushed in a Peter McFarlane set of 12 by 20-in. rolls, the product of which is elevated to the ore bins, and thence through a Denver ore-feeder to the Richards' jig. The jig middlings are reground in a Denver quartz mill to 30 mesh. This pulp is concentrated by an Isbell table, the slime from which is conveyed by the diaphragm pump to Monell slimers, the overflow slimes from the Monell passing to the canvas plates. By all this equipment four classes of product are made: a coarse jig product, a finer jig hutch product, an Isbell table concentrate, and the slime concentrates collected by Monell tables and canvas plates. This mill is said to be making a saving of 84.3% of the assay value of the ore, the heads running 1.30% tungsten, the tails 0.22%. The jig product runs 48.3%, table concentrates 16.75%, slime product 30.2%.

Boyd Mill.

This mill, situated at Boulder, is operated by the Vasco Mining Co. It is in charge of Henry Kautzsch, and is treating a small tonnage of ferberite ore, ranging from 2 to 45%, making products running 55 to 60% WO_3 . The ore is crushed at the sampling plant, and as it comes to the Boyd mill it is passed to jigs in which a coarse product is made. The jig hutch is re-concentrated over tables. The jig tailings are run through batteries of stamps. The middlings from Wilfley and Card tables are reground in a ball mill, then re-concentrated over tables. The Monell slimers handle the fine slimes from the tables, and Monell tailings are retreated on the canvas plates, of which there are 16 in first set and 14 in other.

The Luckie Two.

H. B. Holmes is manager of Luckie Two Tungsten Co., which works its mines up Boulder creek, and operates a concentrating mill in Boulder. The ore, like most of the tungsten ores of Boulder county, is a ferberite, or tungstate of iron. The mill is running on 10 tons per day of ore that carries 6 to 7%, and pro-

duces concentrates that run 60% WO_3 . The ore is reduced to $\frac{1}{4}$ -in. size by a crusher and set of rolls, and is then pulverized by Denver Quartz mills to the mesh required for Wilfley tables and Monell slimers. A classifier is used between the quartz mills and tables. The slimer tailings pass to the canvas plant, containing 2400 sq. ft. of canvas.

Black Metal.

The Black Metal Reduction Co. has in operation at Boulder a plant for the production of pure tungstic acid from the 60% tungsten concentrates of the district. The product turned out is said to rank high among those who use tungstic acid. W. B. Stoddard

DRILL COLUMN HOIST IN TUNGSTEN MINE.

is manager for the company. Prof. Ira M. DeLong, of the state University, is concerned in the plant, appliances and chemical methods.

Rollinsville Mill.

The Rare Metals Ore Co. is operating a custom sampler and reduction plant at Rollinsville. The mill capacity is 50 tons per day, and is being operated at about that tonnage. Rollinsville is on the Moffat railroad, and is 4 miles south of Nederland. The company buys ores running 2 to 15% tungsten, and concentrates them to a marketable product. The ferberite, which is the most prevalent of the tungsten ores of

this locality, is said to be the most in demand by consumers. A recent shipment from this mill showed the following contents by analysis: Tungsten, 66.85%; iron, 18.48%; sulphur, 0.98%; phosphorus, 0.0063%; silica, 3.95%; tin, a trace; manganese, 0.25%. The mill, which was built by Colorado Iron Works, is equipped for pulverizing by a crusher, rolls and a ball mill; and for concentration by jigs, and Wilfley and Deister tables. Included are classifiers and Callow tanks. Nelson Franklin, formerly identified with ore sampling in Black Hawk and Cripple Creek, is manager. The officers of this company are: Guilford S. Wood, president; Irving T. Snyder, vice-president; A. J. Zang, who was treasurer, recently passed away; Geo. A. Stahl, secretary. This company is closely affiliated with the Vindicator Con. Gold Mining Co., owner of the Vindicator and Golden Cycle mines, Cripple Creek district.

Primos.

The Primos Mining Co., controlled by Primos Chemical Co., is operating a large mill for the concentration of tungsten ores, same being situated at Lakewood, 4 miles north of Nederland.

Important Mining Matters Before American Mining Congress.

"Had the present coal production of various Western states been under a federal leasing system at the lowest rate of royalty which has ever been considered, such a state for instance as Colorado would now be paying upon its present coal production approximately \$250,000 annually to the federal government, and the state would have been deprived of whatever taxes it now receives from its coal resources."

This statement is made by J. F. Callbreath, secretary of the American Mining Congress, who has just returned from a trip to the west in the interest of the 19th annual convention to be held at Chicago in November.

Elaborating this thought, Mr. Callbreath went on to state that under a federal leasing system, at the lowest rate of royalty which has ever been considered, Wyoming would be paying upon its present coal production approximately \$125,000 annually; Washington, \$160,000; Utah, \$150,000; Montana, \$155,000, and New Mexico, \$50,000 annually.

"The convention of the American Mining Congress," says Mr. Callbreath, "will afford an ideal opportunity for the west to present its claims to representatives from the eastern mining states whose congressional representation acting with western members can prevent unwise legislation and bring about the enactment of laws which will stimulate the development of western resources.

"Whether the Ferris land leasing bills shall be enacted, or whether the amendments made by the senate committee shall prevail, is of vital importance to the west. Whether the California oil claimants whose

rights are based on a compliance with the U. S. Land Office regulations then in force, shall be robbed of their property without right of appeal to the courts, as the Alaskan coal claimants have been, is of vital importance to every loyal citizen.

"Whether the resources of the west are to pay endless tribute to the government through a federal leasing system, or whether these resources shall be subject to the taxing power of the states, concern directly every taxpayer. Whether a cumbersome agency 2000 miles away, without knowledge of conditions, shall control western development, or whether the basic principle of republican government, home rule, shall prevail, and our development be controlled by those who know, is one of the most important and pressing questions now facing the west.

"The coming session of congress at Washington will probably pass finally upon these questions. The leasing bills have passed the house of representatives and are now before the senate. Western senators are entitled to great credit for the work thus far accomplished.

"The senate is likely to approve the work of its committees; but unless the west shall rally to the support of the senate committee recommendations, there is great danger that the house of representatives may refuse its approval. Legislation along several lines of great importance to the west will be thoroughly discussed by those interested in the development of the western states."

Discussing the various issues now pending before congress, Mr. Callbreath said, "The next session of congress will have under consideration the Foster bill, for revision of mineral land laws of the west."

It will be recalled that a bill to investigate conditions at its public hearing in the western mining centers, making recommendations to congress, was introduced by Senator Smoot, and passed the senate, but failed to receive the approval of the house committee on mines and mining.

"In its stead Dr. Foster, chairman of the committee, introduced a bill intended to meet the requirements without the preliminary work of the commission. This bill was severely criticized by the west. A thorough discussion of the subject will take place at the Chicago convention. Dr. Foster himself will lead the discussion and convey the plan he proposes. The discussion will be lively if the critics of his bill meet him on the floor."

Tin exports from the Federated Malay States in July are returned as 3499 tons, against 3544 tons and 4582 tons for July in 1915 and 1914 respectively. The total to August 1, 1916, is given as 25,224 tons, against 26,862 tons to August 1, 1915, and 29,484 tons to August 1, 1914.

Zinc dust oxidizes rapidly, absorbs hydrogen and is chemically very active, resulting at times in spontaneous combustion or explosion.

Self-Lubricating and Cleaning Roller Bearing.

A roller bearing in which there is free circulation of the lubricant and at the same time a means for dirt and grit to work out from among the rollers, has been patented by three Indiana men—M. O. Reeves, E. Lewellen and L. P. Everroad, all of Columbus. Their patent has been assigned to the Reeves Pulley Co. of Columbus.

As shown in the two sectional views, the casing of cast iron is made with annular openings at each end in which run shoulders or collars on the shaft.

SELF-LUBRICATING AND CLEANING ROLLER BEARING.

This construction prevents the lubricant from escaping from the bearing.

The rollers themselves, as seen in the cross-section, are hollow, the interiors being filled with felt or other absorbent material. Holes are drilled in the sides of the rollers, as shown in the lower part of the longitudinal view.

Oil from the cups in the upper half of the casing flows down to the ends of the rollers and then through the absorbent material, working out to the surface through the holes. Dirt or grit which gets into the rollers is naturally worked downward by gravity and the rolling action, and finally finds lodgement in the wells in the bottom of the lower half of the casing, from which it is readily removed.

Fluxes are divided into three classes—acid, basic and neutral. Silica is the common acid flux. The basic fluxes are lime, magnesia, ferrous oxide, manganese oxide and alumina, which is feebly basic. Fluorspar is a neutral flux.

The Man Who Made Granby.

After having been identified with the management of the Granby Con. Mining, Smelting & Power Co. ever since it was organized, Jay P. Graves of Spokane, former vice-president and managing director of the corporation, has retired from the directorate, and Henry Bruere was chosen to succeed him at the annual meeting in New York on Wednesday, Oct. 4.

It was due to the personal efforts of Mr. Graves that the Granby came into existence, and as vice-president and general manager he was largely responsible for making the corporation one of the most important producers of copper on the American continent. With a small coterie of Spokane men, who, like himself, had confidence in the future of the mining industry in British Columbia, he organized the company, took over the initial holdings that eventually became the nucleus of the mammoth mining and smelting enterprise, and personally enlisted eastern Canadian capital in financing the venture.

This was but the beginning of the difficulties that beset the undertaking, however, and it was as vice-president and general manager of the operating company that Mr. Graves distinguished himself as an executive and a practical mining man of rare ability. Transportation was the vital feature of the situation after the company began producing, and through his efforts alone the Canadian Pacific and Great Northern Railway companies were induced to provide rail communication between the original mines and smelter in the Phoenix and Grand Forks districts, making it possible to get coke and other supplies into the smelter and the ore from the properties to the plant, besides furnishing an outlet to market for the blister copper product.

Having accomplished this, Mr. Graves then turned his attention to increasing the scope of the company's activities, and his success in this endeavor is indicated by the fact that the concern now has important copper-gold properties in different parts of Alaska and British Columbia, and two smelters, one at Anyox and the other at Grand Forks, that are producing approximately 4,000,000 lbs. of blister copper monthly, in addition to a considerable gold and silver output. The corporation is paying 8% annually in dividend on the issued capitalization of \$14,998,500, divided into 149,985 shares at \$100 each, and the surplus on June 30, 1916, was officially reported at \$2,919,384.

At the annual election W. H. Nichols was continued as president and Frank M. Sylvester as vice-president and managing director, a position to which he was advanced 2 years ago when Mr. Graves resigned as managing director. E. P. Earle, W. H. Robinson and Edwin Thorne were chosen vice-presidents; G. W. Woster, treasurer, and Northrup Fowler, secretary. The officers, with J. B. F. Herreshoff, B. Hochschild, William A. Paine and Sanford Steele, New York, and M. K. Rodgers, Brentwood Park, Cal., compose the directorate.

Ore Sampling Conditions in the West

T. R. WOODBRIDGE.*

(Continued from Page 621.)

The Snyder machine is in use at one plant examined, that shown in flow sheet. This machine (Figs. 1 and 2) consists of a cast-iron plate *a*, revolving in a vertical plane on the axis *b*. The spout that passes through the plate receives the sample portion from an inclined delivery chute. When the sample spout is not beneath the ore chute, the ore impinges against the plate and is thereby thrown back into the reject receptacle. Being made of cast iron, these machines have no easily bent or twisted parts, are easily accessible for cleaning and keeping in repair, and, under proper conditions, should give a correct sample. The greatest danger of inaccuracy lies in improper construction. As is shown in Fig. 2, the cutting edges, *ef*, of the sample spout should be parallel and preferably perpendicular to the plate, and the sides of the sample spout should be in planes passing through the center of rotation. With this construction, the opening in

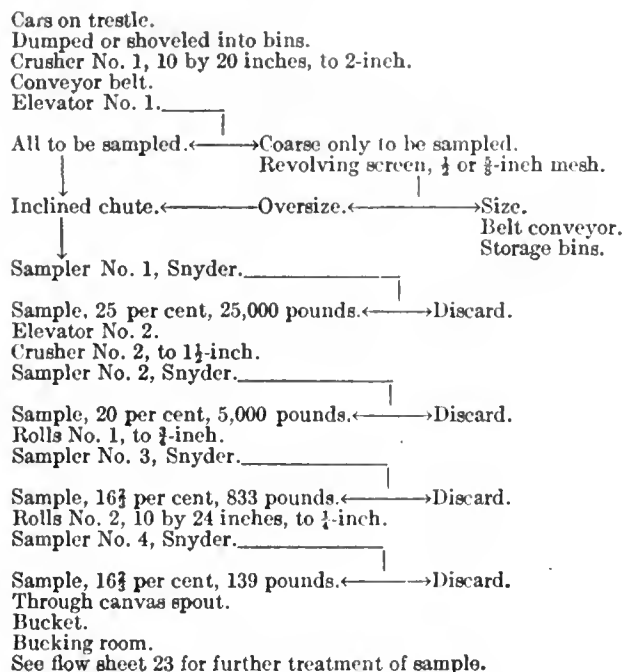

FIG. 1. SNYDER SAMPLER.

FIG. 2. IDEAL SECTION.

the spout will become wider as the edges wear down, but at the same time it will acquire a longer radius of rotation and will consequently continue to cut the same arc in the same period of time. On the other hand, should these sides vary from the construction described, as, for example, should they be parallel or converging toward the bottom, the wearing of the edges will not cause a corresponding widening of the spout, and the greater the wear the less will be the proportion taken for the sample at that point. If the sides spread more than they should at the bottom, the wear will cause an increasing proportion to be taken in the sample. As the delivery chute is at an angle to the horizontal, the coarser particles will be delivered nearer to *f* and the finer particles will fall near *e*, and therefore the edges of the sample spout will show a greater wear at *f*, as shown by the dotted line *eg*. An error may also be caused

by some of the fine ore that ordinarily would fall into the sample spout, adhering for a time to the plate *a*, and then dropping into the reject, or some of the fine ore that ordinarily would fall into the reject dropping into the sample spout. This occurs principally with damp and sticky ores. Owing to the slowness of rotation, it may be questioned whether the sample is taken frequently enough. This error is largely overcome by having two, three or four sample spouts cut in the disk, though this increases the probability of error through sticky ore, as suggested.

A type of mechanical sampling devices is represented by the various time samplers that have either a rotating or an oscillating motion. These samplers are so constructed and operated that, during one-twentieth to one-fifth of the time of a single rotation or oscilla-

FLOW SHEET USING SNYDER METHOD.

tion the entire stream of ore is diverted for the sample, and during the balance of the period the entire stream of ore falls into the reject receptacle.

This type has certain special advantages in addition to those already ascribed to mechanical samplers. With proper construction and operation, the manner of delivering the ore is theoretically unimportant. Even though the ore be screened and the fine and coarse delivered to the sample spout from opposite sides of the chute, no error should occur, because the machine cuts across the entire stream, consequently both the sample and reject are under every section of the stream for the same proportion of the time. Owing to the sample spouts being wider than is possible in the riffle system, there is less danger of clogging and the entire machine can be made more readily accessible for clean-

*U. S. Bureau of Mines; excerpts from advance proofs, Technical Paper 86.

ing and repairing. The particular disadvantage of this class is, as already mentioned, that a machine may be as easily built to deliver a deceptive or unreliable sample as a reliable one.

Bricking a Shaft Down from the Top.

This sounds like an impossibility, but Marcel Gilicieux of Leige, Belgium, has hit upon a plan by which it can be done. The bricks, which are curved to the arc of the circle desired for the lining of the shaft, are formed on their outer surfaces with hook-like projections and annular recesses. The longitudinal section of the shaft here shown explains this construction more clearly than words. The top circle of bricks is hung from a ring which forms the mouth of the well or shaft, or from the top edge of

METHOD FOR BRICKING A SHAFT DOWNWARD.

a chimney if it is desired to line it in this manner. As the excavation of the well or shaft proceeds downward, another circle of bricks is hung by the hooks, fitting into the annular recesses in the first circle. Soil is then worked in back of the bricks and concrete also poured in behind them, through apertures left in the bricks. The concrete, when it sets, then holds the bricks to the sides of the shaft so that as the shaft proceeds to a great depth, no excessive weight need be supported by the first circle.

Twenty-five hundred coal miners in the Mercer-Butler bituminous coal district of Pennsylvania have been granted a voluntary increase in wages of approximately 10%.

With 15,834 men employed and 252 mines contributing, Iowa produced 7,530,088 tons of coal in 1915.

Concreting in Cold Weather.

Concrete work can be carried on successfully in cold weather. All that is necessary is to heat the sand and pebbles or broken stone and mixing water so that the concrete mixture will have a certain minimum temperature, then to place the concrete quickly and maintain the heat until early hardening has been completed. This does not mean that there are no limitations to the practicability of doing concrete work in cold weather, but that if a few simple precautions and protective measures are used, winter concrete work will be as successful as that done in warm weather.

Many contractors have found their working season profitably lengthened by using these precautions and protective measures. This means that men and equipment can be kept profitably employed almost regardless of season. In this way the contractor can keep his efficient organization together. The resulting advantages are far greater than the seeming disadvantages—principal among which is that applying the necessary precautions slightly increases the cost of cold weather work. This, however, is usually offset by the builder's willingness to pay for the privilege of having the use of his building or structure earlier than would be possible if work were postponed until warm weather.

It is well to remember that during the first few days following the placing of concrete, alternate freezing and thawing at comparatively short intervals will damage it.

Remember, therefore, that it is necessary to so mix, place and protect the concrete that early hardening will be complete before the work is exposed to freezing temperatures.

To do this:

- (1) Sand and pebbles or broken stone used must be free from frost or lumps of frozen material.
- (2) If these materials contain frost or frozen lumps, thaw them out before using.
- (3) As cement forms but a relatively small bulk of the material in any batch of concrete, it need not be heated.
- (4) Mixing water should always be heated.

Although adding common salt to mixing water will prevent freezing of concrete that has not hardened, there is a limit to the quantity of salt which may be added if the final strength of the concrete is not to be affected. Salt simply lowers the freezing point of the mixing water; it does not supply what is most needed—heat and warmth. It delays, instead of hastens, the hardening of the concrete.

Sand and pebbles or broken stone and mixing water must be heated so that the concrete when placed, shall have a temperature of from 75 to 80°.

Some sands are injured by too much heat. The same applies to certain varieties of pebbles and broken stone. A temperature not exceeding 150° Fahrenheit will generally prove the most satisfactory.

Recent Developments in Drilling Apparatus

Improvements of considerable importance to drilling apparatus have been made recently by two Denver men—Niels C. Mickelson and William A. Smith. The former has worked out a simple but practical method for cleaning drill hole—compressed air or steam being introduced through the drilling apparatus and readily controllable as to volume. The latter has confined his efforts to the design of a drill which is rotated at the same time that it is reciprocated; this

the pressure behind auxiliary piston (22). Then the plunger is withdrawn and the point (24) pulled out of the opening, leaving it unobstructed and unthrottled for passage through to the drill point.

Attachment for Rotating a Drill.

One form of Smith's rotating apparatus is shown

FIG. 1.

rotation being accomplished by steam or air-driven auxiliary apparatus, which is a part of the drill itself. He has designed two methods of operating this auxiliary device.

Drill Hole Cleanser.

Mickelson's drill is shown in Fig. 1, a longitudinal section of the device complete, and also an enlarged detail of the supplemental cylinder and piston for operating the controlling valve.

The hammer piston which operates the drill (5), and (10) being an internal compression chamber which receives the air or steam from the outside source. It will be seen that the piston head is hollow, also the drill, a sort of plunger, like the firing pin of a rifle extending clear through from the piston head. This plunger has a piston head of its own (22) at the rear,

FIG. 2.

operating in a small auxiliary cylinder. Normally this plunger is in the position shown, because there is little back pressure on the point (24), while full pressure is exerted on the head (22). In this position some of the air or steam is admitted to the hollow drill past the point (24), and blows out the cuttings at a moderate rate. If the operator wishes to inject a stronger jet—the full pressure of the main source—he presses the cap (28) which opens the port (26) and relieves

FIG. 3.

in Fig. 2. The drill point is shown (11). The cylinder is the hammer (10) piston for driving it. A casing (22) is clamped around the drill, from which

FIG. 4.

extends an auxiliary cylinder (25) with air or steam inlet. The arrangement of this casing and cylinder is better shown in Fig. 3.

Here it will be seen that the plunger in the aux-

iliary cylinder carries a gear rack, the teeth of which engage those of a gear mounted on the main drill. When the operator turns on the air to the auxiliary cylinder, its piston, working back and forth, oscillates the drilling apparatus and consequently the bit.

Fig. 4 shows a different way for accomplishing practically the same results in drilling, except that the

drill is completely and continuously revolved. Here a worm gear is used to mesh with the gear on the main drill. This worm is turned by a small rotary motor as shown in the detail view, steam or air being admitted at the right and turning the two intermeshing fluted cylinders, one of which is connected with the worm shaft.

New Development in the Copper Leaching Art

In testing various ores for the Koenig method of extracting precious metals through process of cyaniding, it has been found oftentimes ores carrying a considerable amount of copper. In ores of this character, the copper always interfered with cyaniding, and, even if it were possible to overcome such interference, the copper became a total loss. By very exhaustive experimenting for the sole purpose of overcoming and eliminating the interference of copper with the cyanide solution, and at the same time to save the copper values, metallurgists of the Koenig Cyaniding Process Co. finally discovered the means by which to overcome both ends, by making the drum adaptable to the most efficient copper recovery process.

In order to leach copper by means of its new method, it became necessary to construct all parts of the drum coming into direct contact with sulphuric acid used as dissolvent of copper, absolutely acid proof. It is now claimed to be able to extract the copper in a very similar, almost identical manner, by using sulphuric acid instead of cyanide.

The filtering material with which the drums are lined, is in every respect, acid proof, and therefore, it was unnecessary to make any changes for leaching copper. In order to utilize the present advantages of the method for copper leaching, it was only necessary to render the interior steel construction of the drums acid proof also. This has been accomplished by coating all of the metallic parts of the drums exposed to the solution of sulphuric acid, with lead, and this is being done by a newly invented and patented electrical process. This lead coating in the drums withstands the acid perfectly. The cost of lead lining is so inexpensive that the difference in price between the standard recovery drums and the lead-coated ones is but very slight. The lead-coated drums can be used for the recovery of copper, as well as for the recovery of gold, silver and platinum.

Ore containing copper, after being ground to a mesh most suitable to the quickest and highest extraction, is dumped into the drum, the sulphuric solution added, and then start agitation by revolving the drum.

Steam can also be added to heat the solution, as heated solution produces a quickening effect of dissolving copper, and in sulphide ores, steam will liberate and create sulphuric acid. Copper dissolves very readily in sulphuric solution, and the time of agitation is about one hour. After finishing agitation, filtration

is begun, and it requires but very brief time to filter out all of the copper pregnant solution even from very slimy ore. The copper then can be recovered from the solution either by precipitation on scrap iron or by electricity. The copper extraction in all of the experiments has never been less than 95%, and at most times just a trace was left.

The standard drum is 15 ft. long and 6 ft. diameter, and has in the gold recovery process a daily capacity of about 40 tons; one drum of these dimensions in copper treatment, will have a capacity from 80 to 100 tons per 24 hours.

In operation, if the lead-lined drum is to be used for extracting precious metals and copper, the copper is leached out first. Apply thorough wash to remove sulphuric acid in order to prevent the interference of same with the cyanide solution; then without stopping the revolving of the drum, sluice off the cake by a back-wash, add cyanide solution and start agitation, filtering and washing in the same manner as before; sluice out the barren pulp and stop revolving, and the drum is again ready to take in a new charge.

The copper leaching is generally perfected in one-half the time of the cyaniding, therefore, where a larger tonnage is to be handled, it is preferable to use a battery of two cyaniding drums to one copper leaching drum.

To leach one charge of copper in the lead-lined drum, and to conduct the gold and silver tailings therefrom to the cyaniding drum, it takes from 1½ to 2½ hours. After completing the process, in order to extract the precious metals (gold, silver and platinum) the whole cycle of agitation, filtering and washing requires about 3 hours.

While the gold recovery drum is being agitated, another charge can be leached in the copper drum, and the pulp conducted into the second drum. In this manner three drums can be operated simultaneously, and thereby about 100 tons per day of ores containing copper and precious metals can be treated very effectively.

By this process it has been found that in gold and silver ores containing only ½ of 1% of copper the recovery of copper alone will fully pay for the complete treatment of copper, gold and silver.

The borax deposits of the United States are of great extent and there seems to be little danger of their exhaustion.

Mill of the Nevada Packard Mines Co.

The Nevada Packard Mines Co., Reno, Nev., is operating a mine and mill at Lower Rochester, the mine being near the eastern limits of Rochester's mineralized zone. The principal vein is on the contact between rhyolite and lime, and has a width of 25 ft. The ore, as broken, without sorting, is said to mill \$10 in gold and silver. The gold is finely disseminated, and the silver occurs as a chloride, in a gangue of quartz and schist. What seems an overflow from the

ery of 96% is said to be made. The company's cost sheet places the average mining cost at \$1.23 per ton of ore, and milling costs at \$1.27. Development charges, incidental to mine production, are placed at \$1.34 per ton of ore milled. The mill has a gyratory crusher, a set of rolls, two tube mills, leaching tanks, Oliver filter, and Merrill precipitating presses. The pulp passing from tube mills is 200 mesh. Pebbles are being replaced by manganese steel

MARCY MILLS IN CYANIDE PLANT OF NEVADA PACKARD MINES.

contact vein has mineralized the surface rhyolite and schist, forming a deposit of considerable extent, assaying about \$12 in gold and silver. This deposit is being mined by quarrying methods. It is said to extend 600 ft. in length, 50 ft. wide, and excavations in ore have reached a depth of about 10 ft. Shipments last year of selected ore, amounting to 2300 tons, sampled \$48.

The mill, equipped for crushing, fine pulverizing and cyanidation, was completed and started last December, and is now treating 90 to 100 tons per day of ore running \$12 to \$14. The ore is well suited to extraction of metals by cyanide treatment, and a recov-

balls in the tubes. Water supply is brought in for mill and domestic use through a 1½-mile line of 4-in. steel pipe from springs, under 600-ft. head.

The officers of the company are: Mark Walser, president; Jacob Nolde, vice-president; Frank Margrave, secretary; J. W. Wilkey, superintendent. All machinery is operated by electric power.

Researches on the treatment of low-grade ores have been rich in results, particularly with respect to gold and copper-bearing ores. Perfection, however, has not yet been reached and there are still attractive fields of investigation yet to be explored.

The "Combination Shot."

S. R. RUSSELL.

In some of the coal mines of this country, especially those in the anthracite field, the practice of making what is known as the "combination shot" is common. It is so called because a charge of dynamite and a charge of blasting powder are used in the same bore hole. One or more cartridges of 40% dynamite is loaded at the point of the hole and then a charge of blasting powder on top of this. Sometimes a blasting cap is inserted in the dynamite cartridge next to the blasting powder to insure detonation and often not.

The blasting powder is ignited either by fuse or miner's quib, the explosion and heat of the blasting powder being depended upon to detonate the dynamite. The miner believes that by loading holes in this manner he is assured that the hole will break clear to the point on account of the extra strength and extreme quickness of the dynamite.

Laws have been passed and are still in the mining laws prohibiting the making of combination shots, but the reprehensible practice is still employed by the miners to a considerable extent, with or without the assent of the operators.

According to the best authorities and theory, the combination shot is both dangerous and inefficient. It is very probable that in such shots, the dynamite is set on fire by the blasting powder, burns for a while, then upon reaching the critical temperature, explodes. It may happen that the burden of coal on the hole is entirely moved by the force of the blasting powder alone, in which case the dynamite burns up in the open, doing no useful work. If, however, a blasting cap has been primed in it, it burns until the fire reaches the blasting cap when it explodes in the open, doing no work but presenting many dangerous possibilities. The fumes from burning dynamite are extremely poisonous and dangerous, which is another reason for not using the combination shot.

There is such a wide variation between the velocities of detonation of blasting powder and dynamite that little benefit is obtained from the explosion of the dynamite. The combination as practiced is really theoretically reversed as it would probably do more good to make the bulk of the charge blasting powder and detonate it with dynamite, having a blasting cap and fuse connection in dynamite cartridge.

The use of the combination shot should not be allowed not only because it is inefficient, but especially on the ground of safety.

Allis-Chalmers is Prosperous.

The Allis-Chalmers Mfg. Co. is enjoying unusual prosperity founded upon a wise development of its resources and products. The aim of the present administration has been to perfect and enlarge the lines for which there is a constant demand at home, and at

the same time to improve the manufacturing facilities so that satisfactory prices and deliveries could be made upon a greatly increased output. The results of this policy are now seen in the large volume of orders for standard product at very satisfactory prices.

The company handled its large orders for machining projectiles so that they not only interfered in no way with its regular work, but all additions to plant and equipment were made with a view to their ultimate utilization in the standard business of the company. This is now being done and the capacity of the company increased accordingly.

One important new line which the company has recently taken up is that of farm tractors, and from the success of these tractors at the demonstrations and in actual service this year, a large annual business seems assured.

At the present time, the unfilled orders on the books of the company approximate \$12,000,000, all for its standard products, which cover practically all phases of the mining and manufacturing development of the country.

There are no labor troubles at any of its plants, and it is increasing steadily the number of its employes, so that it is able to give good service to all customers.

Cosna-Nowitna Region, Alaska.

In central Alaska south of the Yukon river there is a large area which prior to 1915 was practically unknown. In the summer of 1915 a small Survey party in charge of H. M. Eakin made a rapid exploration from Tanana river at Cosna to the headwaters of Nowitna river and thence down the Nowitna to the Yukon. A preliminary statement of the important geologic and topographic observations made on that expedition has recently been published as part of Bulletin 642, entitled "Exploration in the Cosna-Nowitna Region." Much time has been spent by a few prospectors in a search for placer gold on Nowitna river, but so far as is known the occurrence of commercial placers in that region has not been demonstrated. In much of the region prospecting is beset with considerable difficulty, owing to the great depth and breadth of the alluvial filling in the larger valleys. Although no lodes have yet been discovered the evidence available seems to suggest that the gold in the bedrock was probably introduced as a result of the igneous activities that produced the monzonites and granites, so that gold is most likely to be found near these intrusive masses. The map accompanying this report indicates the distribution of these intrusive rocks as well as of the other geologic formations.

The equipment of a mine should be up to the requirements for economical operation to a capacity which prospecting and development work has assured, but to equip lavishly before that stage has been reached is the height of folly.

What the Mining Companies are Doing

Mason Valley Mines Co., Nevada.

The balance sheet of the company shows as follows as at August 31, 1916:

Assets—	
Mines, claims and land.....	\$956,318.21
Expenditures on properties under option.....	14,030.81
Less sale of Gregory ranch.....	\$ 16,000.00
Mine and smelter bldgs. and equipment.....	667,742.68
	\$ 954,349.02
Mines, claims and plant, total.....	\$1,622,091.70
Government land scrip.....	12,000.00
Prepaid insurance.....	1,481.47
Sinking fund bonds.....	4,028.40
Current assets:	
Inventory of ore, matte, flue dust.....	\$ 9,883.09
Inventory of supplies.....	40,835.84
Accounts receivable and advances.....	10,325.19
Gregory ranch payment due Nov. 1.....	10,000.00
Securities owned at cost.....	257,330.90
Accrued interest (due Nov. 1).....	4,340.00
Cash in banks.....	6,958.89
	336,772.01
	\$1,976,373.58
Liabilities—	
Capital stock:	
Authorized 500,000 shares at \$5 par.....	
Issued 155,750 shares at \$5 par.....	\$ 778,750.00
First mortgage 6% convertible gold bonds.....	869,500.00
Current liabilities:	
Sundry creditors and taxes accrued.....	\$ 15,565.91
Accrued int. on bonds (due Oct. 1).....	21,737.50
	37,303.41
Reserve for doubtful accounts.....	\$ 10,000.00
Surplus accounts:	
Balance Jan. 1, 1916.....	\$328,296.51
Net loss 8 mos. per profit and loss acct.....	280,820.17
	\$1,976,373.58
Income:	
Interest received, net.....	\$ 7,660.39
Interest accrued.....	4,340.00
Rent.....	15.00
Income from Gregory ranch, net.....	118.45
	\$ 12,133.84
Expenses:	
Loss on purchase and sale of securities.....	\$ 1,241.05
Taxes, insurance, watchmen and other mine and smelter expenses.....	16,720.06
Examinations of properties and engineering.....	11,804.22
Legal and New York office expenses.....	5,914.55
Federal income tax.....	120.30
Interest on bonds.....	34,780.00
	69,710.18
Net loss for 8 months carried to surplus account.....	\$ 57,576.34

Greene-Cananea.

Greene-Cananea Copper Co.'s September results compare as follows:

	Copper, lbs.	Silver, ozs.	Gold, ozs.
September.....	4,906,600	153,495	814
August.....	5,000,000	144,480	862
July.....	4,600,000	116,800	745
June.....	4,500,000	123,700	800
May.....	5,948,000	183,809	1,199
April.....	5,348,000	205,748	1,193
March.....	5,358,000	200,709	1,146
February.....	5,180,000	181,895	984
January,*.....	3,348,000	113,691	716

*Does not include custom ores.

It is expected that October production will exceed 5,000,000 lbs. Under existing conditions in Mexico this output is satisfactory to the management, although each new tax imposed in Mexico adds to costs and this is now around 11 cts. a pound.

Tennessee Copper.

Under the underwriting agreement which is now being arranged for issuance of 200,000 shares of Tennessee Copper new stock, the bankers, J. S. Bache & Co. and Adolph Lewisohn & Sons, will pay \$14 a share for the stock. Members of the underwriting syndicate will pay \$15 a share, and stock will be offered to shareholders at \$16 a share.

One of the purposes for which new capital is being raised is to provide funds to settle the matter of advances on this

contract. Russia advanced Tennessee Copper approximately \$1,000,000, and while the company still contends that the contract should be continued in force, if Russia can be induced to compromise on a satisfactory basis there is no question that a refund of part of this sum will be made, and the contract abandoned—as it virtually is already.

Suits are pending against the company for over \$1,000,000. It is possible some of these may also be compromised, but it is intimated others will be fought through the courts, as the management of Tennessee is confident of ultimate result. The matter of insurance on the burned plant, involving over \$500,000, will almost certainly be carried to the courts.

If Tennessee Copper can settle all its existing difficulties, it should be able to report fair earnings on its increased capital, for some time at any rate. Its present profits from copper would be equivalent to about 15% annually, or \$3.75 a share, on the larger capital; while the acid business should show a substantial profit if unprofitable contracts are done away with.

Butte & Superior, Mont.

Butte & Superior returned in September to a normal rate of production, the figures comparing with the same months in previous years as follows:

September—	Tons milled.	Recovery, %	Lbs. zinc in concentrates.
1916.....	50,150	93.46	14,496,000
1915.....	40,360	92.79	12,950,000
1914.....	34,850	89.69	11,058,000
1913.....	30,870	90.09	11,553,000

Kennecott Copper.

Kennecott Copper Corporation's production was 8,000,000 lbs. of copper in September, comparing as follows:

	Lbs.		Lbs.
September.....	8,000,000	March.....	10,150,000
August.....	10,200,000	February.....	9,750,000
July.....	10,750,000	January.....	10,000,000
June.....	10,500,000	December.....	10,500,000
May.....	10,500,000	November.....	10,000,000
April.....	10,500,000	October.....	10,000,000

Trinity Copper Co., California.

In contrast to the oft-repeated excuse that Trinity Copper was unable to operate on account of the low price of the metal comes this year's report that the company's idleness was due to the high price of the metal. A "one-man payroll" still exists, for a single miner is doing assessment work. The company had cash on hand at end of year as of Sept. 1 of \$464, compared to \$1234 the year previous. John B. Rock was elected a director succeeding Homer Albers.

The balance sheet of the company as of Sept. 1 shows as follows:

Assets—	
Mining claims.....	\$5,221,000
Development.....	711,980
Expenses.....	218,798
Railway.....	36,500
Cash.....	464
Total.....	\$6,188,742
Liabilities—	
Capital stock.....	\$6,000,000
A. S. & R. account.....	28,548
Ore.....	39,471
Accounts payable.....	120,723
Total.....	\$6,188,742

Nipissing Mines Co., Ontario.

Shipments of bullion by the Nipissing Mines Co. last month were, with two exceptions, the heaviest of the year, totaling \$413,000, against \$447,500 and \$420,900 in April and May, respectively. This bullion came from Nipissing ores and from custom material.

The gross value of September's yield was \$236,833, com-

pared with \$203,000 in the previous month. A record by months of the company's operations so far this year follows:

	Yield		Shipments.
	Gross.	Net.	
January	\$169,800	\$103,600	\$147,000
February	171,800	104,600	309,000
March	170,000	105,500	322,100
April	167,400	101,800	447,500
May	291,900	218,800	420,900
June	294,600	220,688	193,400
July	288,500	218,000	280,100
August	203,800	121,551
September	236,800	413,000

Cedar Talisman Con. Co., Utah.

The company reports its operations for the period, Jan. 1 to April 30, 1916, as follows:

General expense	\$ 430.09
Electric power	208.11
Ore hauling	684.98
Labor	3,359.28
Supplies	852.97
Profit on operation, Jan. 1 to April 30, 1916.....	2,851.37
	<hr/>
Zinc ore sales, lot 10 to 17.....	\$ 8,386.80
	<hr/>
	\$ 8,386.80

Statement showing "loss" on operations May 1 to Sept. 16, 1916:

General expense	\$ 619.16
Electric power	293.21
Ore hauling	704.17
Labor	8,088.54
Insurance	139.75
Supplies	1,911.31
	<hr/>
Zinc ore sales, lot 18 to 21.....	\$11,756.14
Lead ore sales	1,116.56
Loss on operations, May 1 to Sept. 16, 1916.....	2,446.90
	<hr/>
	\$ 8,192.68
Loss on operations, May 1 to Sept. 16, 1916.....	\$ 8,192.68

Supplies and labor unpaid.....	697.59
	<hr/>
	\$ 4,257.50
Balance equals loss May 1 to Sept. 16, 1916.....	\$ 8,192.68

Colorado Fuel & Iron.

Colorado Fuel & Iron Co. reports for the year ended June 30, net profit for dividends was \$2,201,171, which, after deducting 8% for preferred dividends accruing during the year, left a balance equal to \$5.96 per share on the \$34,235,500 common stock. This compares with a deficit of \$334,661 reported in 1915, without any deductions for preferred dividends and \$1,640,229 earned for common, or \$4.79 a share, in 1912, the best previous year.

The company is not as well located as are its competitors to take advantage of present demand for steel from abroad, its distance from the seaboard handicapping it materially in seeking European business. It is believed in the steel trade, however, that it has made large sales of steel to Russia, shipping via Pacific coast points to Vladivostok, and also to Japan.

In the current year Colorado Fuel should do better than in that just reported. The report states that it has business on hand, making capacity operations certain until the close of the current year, and it may be presumed that this business was taken at a scale of prices averaging a good deal higher than those of last year. A better idea of probable profits for the year will be afforded when its report for the September quarter is published.

Granted continued fair earnings for some time, it must be remembered that the company has accumulated 30% in

dividends on its preferred stock, which will have to be cleared off before holders of the junior issue can hope for any return.

Miscellaneous Company Notes.

The United Verde Extension Mining Co. is now producing at a rate of approximately 36,000,000 lbs. of copper annually at a cost of between 7 and 8 cts. a pound. At present the company has its ore treated at a customs plant, but a site has been secured for the erection of a smelter.

At the annual meeting of Utah Apex Mining Co., to be held in Portland, Me., on Nov. 9 stockholders will act on the amendment providing that present capitalization of 600,000 shares, par \$5, be reduced to 125,000 shares, and that the par value be raised to \$25. It also recommends that the number of directors be reduced from nine to not less than five.

In September the Consolidated Arizona Smelting Co. produced approximately 1,170,000 lbs. of copper, according to an official. This is the largest production of any single month in the company's history. Earnings, it is understood, are running at a rate considerably in excess of \$500,000 per annum, which will compare with earnings in 1915 of \$190,000. The company's smelter, which was damaged by fire early last summer, has been repaired.

Should production continue the balance of the year at the present rate Utah Con. will have a total production for the year of about 12,000,000 lbs. of copper and 18,000,000 lbs. of lead. Higher wages and greater cost of materials have naturally been reflected in increased cost of production but estimated earnings of at least double present dividend requirements are possible. In addition to income from its own mining operations, Utah Con. has an investment in 8,250 shares of Anaconda.

*Stockholders of the Consolidated Coppermines Co. are offered \$150,000 7% first mortgage bonds for subscription until Nov. 1 at 90. Additional funds are necessary for the reconstruction of the old Giroux concentrator in order to secure production under the present price of copper, and to utilize it as an experimental plant to determine the best method for the treatment of the company's ores. It is expected that the reconstructed mill will be ready for actual operation by the end of this year.

The property of the Granby Mining & Smelting Co. has been turned over to the American Zinc, Lead & Smelting Co., actual payment for the properties having been made. The acquisition of the property places American Zinc third among the large spelter producers of the country. As a result of the consolidation American Zinc will now be able to produce all grades of spelter. Heretofore the company specialized on its Mascot high-grade and intermediate grades, while Granby has been producing prime western and Granby special.

According to D. C. Jackling, managing director of the Utah Copper Co., the company is earning \$1,000,000 a week and the report for the third quarter will show earnings of \$11,000,000 from Utah Copper and \$2,000,000 from Nevada Con. This makes \$13,000,000 for 13 weeks for the quarter. Utah is producing over 20,000,000 lbs. of copper a month, or 240,000,000 lbs. a year, and the company has about reached its stride. Plant is gradually being added to, and by Jan. 1 next production will show a larger increase. Ray, Chino and Nevada Con. are expected to show greatest production and earnings in their history for third quarter.

Isle Royale's 1916 production, it is estimated, will total better than 12,000,000 lbs. of copper. With high record production and earnings shareholders can look for increased dividends. August operations resulted in 84,000 tons of rock being stamped and as the rock ran about 14 lbs. of refined copper per ton it means that production for that month amounted to over 1,175,000 lbs. of copper. With present production it may safely be estimated that with copper at its present price Isle Royale is earning \$9 per share, or more than twice the present dividend rate. As the company has no large construction expenditures ahead of it and has ample working capital, practically all the current earnings are applicable to dividends. On Aug. 1 cash and copper sold amounted to over \$800,000.

Concernin' Good Roads.

1

Prospectin' round th' mountains for a score of years or so,
Don't always mean a fellow lays aside a lot of dough;
But he gets a deal of knowledge which will assay pretty fair,
An' veins of rich experience he's strikin' everywhere.

2

I don't claim I'm a know-it-all, but sometimes when I see
A mine that ain't apayin' like I think it ought to be,
I feel like my advice would help perhaps to make it pay,
An' folks can take or leave it, for I'm givin' it away.

3

Fer instance, there's th' Silver Gem, as fine a minin' claim
As any in th' mountains more than worthy of her name;
An' yet the ore is trundled down a rough and rotten road,
That makes th' haulin' misery and costs a lot per load.

4

That's just a sample pardner, other mines is just as bad,
It gets me when I think how cheap a good road can be had;
Eventually they'll see it, and figure what they lost
By careless commutation of th' ore production cost.

5

They may be quaint an' picturesque, those rough old mountain trails,
But when yer huntin' dividends, pick out a pair o' rails
That hold a donkey engine, or a solid hard pan road
That's built for motor truckin' an' will stand a powerful load.

American Mining Companies Protest Against Mexican Taxes.

American-Mexican mining and smelting interests to the number of 45, with William Loeb, Jr., of the American Smelting & Refining Co. as chairman, protested to the American members of the American-Mexican commission recently against the prohibitory taxes levied against mining properties in Mexico.

According to the memorandum submitted the 45 companies concerned have sustained a loss in depreciation of property and actual wastage of more than \$7,246,031 in a year of enforced idleness. A wage loss to Mexicans alone amounts to \$16,088,363.

As shown by a census of the operation of the companies, mining and smelting is practically at a standstill. Only 6000 were employed during the first half of 1916, as compared with 62,216 in 1912. Wages were \$3,671,302 as compared with \$18,726,090. Copper production fell off from 74,984 tons to 23,156 tons; zinc from 46,765 tons to 11,183 tons; lead (bullion), 70,939 tons to 2928; silver, 31,892,735 ozs. to 6,200,339 ozs., and gold from 252,843 ozs. to 39,895 ozs., as showing the burden of new taxes as compared with those in force in 1912, total taxes under the Constitutional law of 1912 amounted to \$1,726,600 and under the arbitrary decree of 1916 based on 1912 production amounts to \$7,665,790.

Under existing tax decrees, companies mining and treating large tonnages of low-grade ores, which constitute the most extensive mining operations in Mexico, will be unable to resume operations, since export taxes on the metal, which in the new rates are shown as 10% and 5%, often figure out as high as 50%. This results because no allowance is made for cost of transportation, treatment and marketing.

Those appearing before the commission besides Mr. Loeb were former Judge D. J. Haff, attorney for Phelps, Dodge & Co.; George Young of the Greene-Canaanen Co.; Charles Earle of the United Smelters; Henry Bruere and Julian W. Beatty of American Metals Co. The 45 companies represented a total investment of \$125,000,000.

Present Copper Prices Prove Absence of Manipulation.

The placing of an Italian order for 1,000,000 lbs. copper this week is the chief development in the copper situation. As indicated in our market reports a week ago, business in copper is expected to taper off and the first signs of a receding volume of demand have already been noted. Leading producers assert that incoming business is smaller and it is possible that inactivity will replace the pressure for the metal that has existed since early August. The winding up of the buying movement is welcomed. Orders have been written into the books of the producers that assure them of a protracted period of activity and the

advent of an off-period is not regarded as making for an easier market.

Reviewing what has transpired in the past 10 weeks, the fact that producers held copper below the 30-ct. level stands out prominently in disputing the oft-stated assertion that manipulation of copper prices is at all times rife. When the movement now closing had its inception last August the price of copper held around 26¾ cts., whereas at the winding up of the movement the price stands at 28 cts., indicating an advance of only 1¼ cts. per pound. Taking this advance in contrast with the tremendous business booked since August first it is manifest that the upward movement in prices has been conservative.

Producers can now face the future with definite assuredness of a continued strong market. With over half of their production in the first 6 months of next year already sold and the fact that a considerable amount of domestic buying will develop around January of next year that will easily absorb the balance of the output, the future holds much in store for copper producers.

The termination of the war is not in sight. Generally the viewpoint is accepted that hostilities will continue into 1918, possibly until the summer of that year. The longer the war lasts the greater strength will the copper situation assume. With the profits of 3 years conserved to act as a bulwark against the era of repression that some claim will follow peace, the copper producers are in a position to hold their own until peace demands for copper assume proportions that will necessitate the continuation of capacity production. Europe's reconstruction and the dependence of Europe on the United States for materials for its rehabilitation are the factors that go towards making our present day prosperity stable and sufficiently powerful to resist the reaction that peace will bring.

Wants More Reliable Copper Price Quotations.

And now comes first-hand information as to the general unfairness of the copper metal prices as put forth by Engineering & Mining Journal. As editor of that journal at one time, T. A. Rickard necessarily became familiar with the method by which price quotations were arrived at, and now, as editor of Mining & Scientific Press, he, after all these years, discusses the question editorially. Being good and timely and in order that it may be read by *all* the people vitally interested we gladly give space to the following excerpt:

It is about time to discover some better method of adjustment between buyer and seller. Why not base the wage-scale and the ore-settlement alike on the price that the mining or smelting company gets for its copper? Why depend on the guess of any trade paper when the essential fact can be ascertained by reference to an authentic record, namely, the books of the copper producer or the smelter, as the case may be? What does it matter to the manager of the Little Bullion mine what other people are getting for

their copper? He settles with the smelter on the basis of the price that the smelter is supposed to get for the copper that it buys from him. What does it matter to the copper miner at Bisbee what the Anaconda company gets for its copper? He is only concerned with the price obtained by the particular company that employs him. It may be objected that an interval must elapse between the purchase of custom ore or of miner's labor and the marketing of the copper sold by the one or mined by the other, but that is easily adjusted; pay a nominal price on settlement, and adjust the balance at the end of a specific period. The price at which copper is sold by a given individual or company can be ascertained definitely; the average price at which a variable number of producers sell varying quantities of copper cannot be determined by anybody.

In the event of war it is estimated that this country would need approximately 40,000 tons of nitrogen in the form of 180,000 tons of nitric acid per year. In 1915, enough bituminous coal was mined in the United States to yield, if properly treated, 1,000,000 tons of nitrogen, which could produce 3,600,000 tons of nitric acid, or, on the above basis, enough for 20 years of war. The "if" is the obstacle; our present industrial methods of coal treatment if applied would recover but one-fifth of this nitrogen as nitric acid or, in one year, enough for four years of war, if we were properly to expand and extend these industrial methods and appliances, and also further, to convert the so-recovered ammonia into nitric acid.

Probably at no time in the history of the mining industry have American manufacturers of mining machinery been so prosperous as at the present time. The investment of capital in this industry is enormous and despite the hundreds of immense plants spread all over the United States, great prosperity is evident. That these manufacturers do not have to depend wholly on home consumption is evidenced by the reports of heavy shipments to foreign countries, despite the European war. The fame of "made in the United States," as relating to mining machinery, is reaching farther and farther and today there is no country in which U. S.-made machinery is not seen.

Upon the outcome of the hearing before the Supreme Court of the United States next month depends the very life of the Minerals Separation patents in the United States. As a result of the stay secured in the injunction issued by the United States Court of Delaware the Miami Copper Co. must file with the court a monthly statement of operations so far as it concerns the use of flotation. A bond of \$250,000 is also required. Similar statements to the Montana courts are being made by the Butter & Superior Co. as a result of the decision of the Montana court rendered in favor of Minerals Separation, Ltd.

The importance of an efficient system for keeping track of costs of ore production and treatment cannot be overestimated. Excessive cost at some stage may mean the entire loss of profits. To the careless manager the reason for such losses may remain undetected for lack of a proper system of cost keeping. By the introduction and use of such a system the sources of loss can be readily found and the proper remedies applied.

PERSONAL.

Dr. L. D. Ricketts has been inspecting Arizona copper properties.

A. O. Jacobson has returned to Salt Lake City from his recent eastern visit.

Pope Yeatman recently examined the Cresson mine at Cripple Creek, Colo.

Louis D. Huntoon recently completed an examination of several South Dakota properties.

A. C. Nebeker is superintendent of the Antelope Star property in Beaver county, Utah.

Frank Steffee will supervise the construction of a 500-ton custom mill to be built at Chloride, Ariz.

Morton Webber has completed mine examination work in California and returned to New York.

Wm. O'Neil has been made general manager of the Janet Copper Mining & Milling Co. near Vernal, Utah.

Kirby Thomas recently investigated the iron ore resources of East Tennessee for New York clients.

S. N. Williams, purchasing agent for the Copper Queen Con. Mining Co., is enjoying a vacation on the coast.

Arthur W. Jenks has been appointed smelter superintendent for the Burma Mines Corporation in Burma.

Edmund L. Hiatt has resigned as chief engineer of the Ray Con. Copper Co. to become manager of the Arizona Ray Copper Co.

J. C. Simmons, manager of the Rare Metals Mining & Milling Co., Telluride, Colo., has been in New York city on company business.

W. H. Weyher, general manager of the Silver Reed Mining Co. of Utah, is in Chicago on a vacation trip which will include other eastern cities.

John D. Wanvig, general manager of the Golconda mine, in Mohave county, Arizona, has returned to the property from a several months' vacation.

Louis Procissi, recently on the mining staff of the Copper Range Copper Co., is going to Laredo, Mexico, for the Cia de Minerales y Metales.

J. P. Erisman of Denver, Colo., recently inspected the holdings of the Blue Flag Gold Mining Co. in Idaho, for which company he is general manager.

Max J. Welch has completed the construction of an experimental concentrator for the Cerro de Pasco Copper Co. in Peru and returned to Los Angeles.

A. P. Allen has left the efficiency department of the Calumet & Hecla and has taken a position with the Highland Mining & Development Co., at Ashcroft, B. C.

B. S. Butler, of the U. S. Geological Survey, has completed a detailed study of the Cottonwood-American Fork section of Utah and has returned to Washington, D. C.

Capt. Wm. Corkhill of the Volunteer iron mine, which is located on the Cascade range and which has been shut down as its ore supply is exhausted, has gone to Butte, Mont., to take charge of development work at the North Butte property.

F. Ward Paine is in charge of the diamond drill exploration operations which the Copper Range Con. Co. is now doing upon land under option from the St. Mary's Mineral Land Co. in the copper country.

Andrew N. Fox, for many years advertising manager for the Benjamin Electric Mfg. Co., Chicago, has retired from the electrical business to become president of the R. & F. Copper Co. of Nevada, with headquarters in the Harris Trust

building, Chicago. Years ago Mr. Fox and Thomas C. Rea staked claims to 600 acres of copper prospect property in the Lida mining district. Mr. Rea has continued development on the property each year and now has several shafts and considerable ore developed.

SCHOOLS AND SOCIETIES.

Denver Mining Bureau.—Denver mining men recently organized the Denver Mining Bureau. Following a discussion of the Ferris bill to lease lands containing coal, oil and other minerals, with special reference to its menace to the mining industry, the first board of directors of the bureau were elected: R. A. Parker, L. P. Hammond and P. M. McHugh for the one-year term; W. L. Loveland, D. W. Brunton and O. E. Carey for the two-year term, and Charles A. Chase, R. B. Moore and Fred M. Carroll for three years. The directors then elected Mr. Parker chairman of the bureau, Mr. Hammond vice-chairman, and P. M. McHugh secretary.

NEW PUBLICATIONS.

Gold, Silver and Copper in Alaska in 1915. By Alfred H. Brooks. Washington, D. C., U. S. Geological Survey. Mineral Resources of U. S. I:8; pp. 12.

A general review of the entire territory is made and

Fifth Annual Report by the Director of the Bureau of Mines for the Year Ended June 30, 1915. Washington, D. C., U. S. Bureau of Mines. Report; pp. 106; illustrated.

This report is an account of the work done during the year by the Bureau both in the field and office. A chart is included showing the organization of the Bureau.

Spirit Leveling in South Dakota, 1896 to 1915, Inclusive. By R. B. Marshall. Washington, D. C., U. S. Geological Survey. Bulletin 643; pp. 100.

The elevation and location of bench marks established in primary leveling are given and the bench marks with their elevation and exact location are subdivided according to the quadrangle in which they are located.

Mining on Prince William Sound, Alaska. By Bertrand L. Johnson. Washington, D. C., U. S. Geological Survey. Bulletin 642-D; pp. 9.

A brief account is given of the country and followed by separate accounts of gold and copper mining. Under these two headings the contents is divided into districts under which the operations of the different companies and properties are briefly spoken of.

The Turnagain-Knik Region, Alaska. By Stephen R. Capps. Washington, D. C., U. S. Geological Survey. Bulletin 642-E; pp. 48; illustrated.

Sketch maps, showing the geology, distribution of timber and location of towns, etc., are shown separately. The introduction is a geographic description of the area and this is followed by a description of the geology of the country. Mineral resources, principally gold placers, and gold and silver lodes, are subdivided and reviewed in the concluding pages of the bulletin.

The History and Development of Gold Dredging in Montana. By Hennen Jennings. Washington, D. C., U. S. Bureau of Mines. Bulletin 121; pp. 63; illustrated.

A chapter is included in the bulletin by Charles Janin on "Placer Mining Methods and Operating Costs." Early operations are briefly taken up and followed by a complete description of present and past operations and methods of dredging in the Ruby district. The text is confined mostly to the Conrey Dredging Co., as this company is the principal company in the Ruby district. Cost data and methods of accounting are described, as well as the occurrence of the gravels, dredge construction and operation, etc. The chapter by Charles Janin is more general in its scope and foreign

countries as well as states other than Montana are considered.

Report on the Fertilizer Industry. Washington, D. C., Federal Trade Commission. Report; pp. 269; illustrated.

Tables and composite curves comparing the production of fertilizers from different sources, both natural and artificial, are reproduced, and in general the report is a review of the industry as regards both production and sales. The report was the outcome of a resolution of the U. S. Senate whereby it was authorized to investigate the causes of the advance in prices of ammoniates and nitrates used in the manufacture of fertilizers.

Density and Thermal Expansion of American Petroleum Oils. By H. W. Bearce and E. L. Peffer. Washington, D. C., U. S. Bureau of Standards. Technologic Paper No. 77; pp. 26; illustrated.

The paper gives an account of the experimental work on which are based the expansion tables of Circular No. 57. Detailed descriptions of the methods employed and apparatus used in the determination of the density and thermal expansion of petroleum from the various fields in United States are given. Results, formulas, etc., are also given.

The American Petroleum Industry. By Raymond F. Bacon and William A. Hamor. McGraw-Hill Book Co., New York. Books; Vol. I; pp. 446; Vol. II; pp. 517; illustrated. For sale by Mining World Co., \$5 each.

Vol. I is on the operations and nature of the wells, while Vol. II is mostly confined to "oil refining technology." Much of the information has been obtained from other authors, who have written in some cases special chapters, as well as from U. S. Geological Survey and Bureau of Mines publications. In reviewing the purpose of their work the authors state that they have endeavored to prepare a book of value as a general reference for those engaged in the industry as well as a text for students. The subject matter is essentially descriptive of actual operations and only so much theory is brought out as is of value in bringing about a clear understanding of the description of operations. The book is well illustrated and supplemented with drawings and tables and will be found as complete as the number of pages allotted to the subject will allow.

Anuario de Minería, Metalurgia, Electricidad y demas Industrias de España. By Adriano Contreras and Roman Oriol. The Revista Minera, Madrid, Spain. Book; pp. 1000. For sale by Mining World Co. \$2.

Translated, the title reads, "An Annual Directory of Mines, Metallurgy, Electricity and Commercial Chemistry in Spain." The book has been published annually for the past 20 years and contains a list of all mines, classified according to the metal mined and province in which the mine is located. Metallurgical, electrical and chemical societies, in Spain, with their capitol, address and administrative boards, are also classified, as are chemical and metallurgical plants. A directory of Spanish civil engineers is given and a classification of railroads of interest to mining is made. Fees of the laboratory of the School of Mines for examining and analyzing ore; custom-house duties and commercial treaties; official laws and arrangements referring to the metallurgical and mining industry; commercial arrangements by the government; Spanish industry according to class and provinces; useful and numerous commercial advertisements, etc., are included in the text of this book, which is confined to the country of Spain.

gotten up in a similar manner. The construction, operation, uses and featuring points of each is brought out in the separate texts. Tables and curves are also given of general use in hydraulic and pump designing and work.

Plant and Railroad Oil Storage Systems. S. F. Bowser & Co., Inc., Fort Wayne, Ind. Booklet; pp. 40; illustrated.

Many good-sized views, with brief descriptions, are shown of different departments of the company's plant. Self-measuring pumps and similar devices for drawing specific quantities from the tank by means of the pump only are illustrated and described and oil-filtration and complete storage houses are considered in a like way. In bringing out the use and applicability of the company's appliances views of practical installations are given in preference to lengthy descriptions and discussion.

Brick Making and Clay Working Machinery. The American Clay Machinery Co., Bucyrus, Ohio. Bulletin No. 96; pp. 242; illustrated.

It is often found in mine and plant work that the cost of a machine for making bricks plus the cost of making bricks is cheaper than purchasing the bricks and shipping them in. Such a machine is made by this company, besides a complete line of machinery for large plants. The bulletin describes most of the company's new line of machinery. Each different machine is illustrated, its particular uses noted in a description and followed by complete specifications of the machine in question. In most instances this information is contained in two pages. Cars, trucks, elevators, etc., are included in this line of clay working machinery.

Imperial Welding and Cutting Hand Book. Imperial Brass Mfg. Co., Chicago. Book; pp. 56; illustrated.

Though views and some information regarding the company's equipment are given, the book is not intended as a bulletin or catalog of the company's products. It is rather a complete text on correct welding and cutting practice with the oxy-acetylene torch. Many drawings and illustrations have been inserted to make the description clear. The principles and theory underlying the practice are brought out and descriptions of different outfits and operations accomplished with this system are dealt with. Special attention has been given to making the book of value to the inexperienced and all technical phraseology has been omitted. Many diagrams are also included showing the correct way of using the torch to accomplish different forms of cutting and welding.

Marcy Ball Mill. The Mine & Smelter Supply Co., Denver, Colo. Catalog; pp. 32; illustrated.

The mill, its construction, requirements, particular uses, accomplishments and advantages are taken up in the first pages. They recommend the mill first for 3 or ½-in. feed to 10-mesh direct. Second, for crushing the same feed to as low as 40-mesh and in this case using a hydraulic classifier for returning oversize. Third, in crushing to as low as 100-mesh when a mechanical classifier should be used or combination of the same with screens. In the concluding pages is an article by F. E. Marcy, "Notes on the Practice and Design of Wet-Crushing Ball Mills," which is confined to practical theory. Formulas are derived in the article and reproductions of curves given showing the work done by a Marcy mill and comparing the products from crushers, rolls and ball mills made by expending the same amount of energy.

INDUSTRIAL AND TRADE NOTES.

G. L. Simonds & Co., 230 South La Salle street, Chicago, announces that in the future the company will be known as the Vulcan Fuel Economy Co. The company's specialty is the Vulcan soot cleaner for water tube and tubular boilers.

P. H. Reardon has severed his connection with the General Machinery & Supply Co., San Francisco, having disposed of his interest to his associates. Joseph A. Buckley succeeds Mr. Reardon as president. A. L. Green is vice-president and H. F. Jurs manager.

TRADE PUBLICATIONS.

Centrifugal and Turbine Centrifugal Pumps. A. S. Cameron Steam Pump Works, New York. Bulletins Nos. 151, 152, 153, 154; pp. 52; illustrated.

Bulletin 151 is on the company's turbine centrifugal pump; No. 152, a single-suction volute pump; No. 153, a two-stage house pump; No. 154, a double-suction vertical pump, all being of centrifugal design. Each bulletin is

Late News From the World's Mining Camps

Editorial and Special Correspondence.

ALASKA.

Seward.

A. Clementua, manager of the land and industrial department, has given out the following official account of the government work in rebuilding the Alaska Northern railway, extending the line north from Seward.

The Alaskan Engineering Commission is now employing 525 men and 64 station men in the rejuvenation of the Alaska Northern railway, which was purchased by the Government. The work consists of rebuilding bridges, elimination of high trestles with fills, improvement in the alignment and some slight reduction in the grades. There will be a small reduction in the maximum grades on the 12-Mile and 45-Mile summits. Many of the fills have been widened and considerable ballasting has been done. Across Placer river in front of Spencer glacier, temporary trestles and fills have been made for a distance of over 3000 ft., which will be replaced next year by a permanent trestle raised 10 ft. above the present level of the track. New shear and division dams are being constructed so as to control the waters of the river and to prevent washouts which have been an annual occurrence since the road was constructed. Seventy-five thousand new ties have been laid, and it is contemplated that before the work is finally completed to Mile 71 over 200,000 ties will have been laid.

A machine shop has been built at Seward to replace the one which burned early last year, and all repairs are now being made in that shop.

The road is now in operation to Mile 64 from Seward and a freight train is operated over the line every Sunday and a passenger train on Mondays, Wednesdays and Saturdays. It is expected that the line will be opened and in operation to Kern Creek (Mile 71), the end of the track, by Oct. 20. Kern creek will be a distributing point for that part of the work on Turnagain Arm, which will be done from the Seward end, as well as for points along the Arm, and considerable increase in traffic is expected as soon as the line is completed to that point.

The work is under the supervision of R. J. Weir, engineer in charge, who before being employed by the Commission was a locating and construction engineer with the Southern Pacific railroad in California. He has also charge of the new construction work along Turnagain Arm between Kern and Glacier creek, a distance of 4 miles. This is all expensive rock work and it is estimated that it will cost approximately \$250,000. There are now several station gangs at work on this portion of the line. It is expected that it will be completed by spring when the work along Turnagain Arm will be prosecuted as fast as funds and material will permit.

Altogether contracts have been let at Seward to station men aggregating \$150,000 on work between Seward and Glacier creek, and in addition to that the monthly pay roll of the Alaskan Engineering Commission at Seward now amounts to between \$40,000 and \$50,000.

ARIZONA.

Hayden.

Plans for the construction of a \$500,000 mill, to re-treat the vast amount of tailings from the Ray Con. Copper Co.'s mill, are now being prepared. The new plant, which will be erected on the banks of the Gila close to the great tailings

dump, will have a daily capacity of 6000 tons, and will employ about 250 men. The tailings dump contains a large tonnage of copper, but in the form of an extremely low-grade material, the copper content being a fraction of 1%. The fact that even this waste material is to be recovered is another demonstration of the economical methods which the company is putting into operation in extracting the copper from the low-grade ores. News that a new mill giving employment to hundreds more men is to be erected at Hayden will be received jubilantly by residents of the smelter city and by the entire district, for while Hayden will in the main profit most from the erection of the new mill, it all means a greater district in the Pinals. Erection of the new re-treating plant at a cost of half a million dollars will give employment to hundreds of workmen, while the increased capacity of the Hayden smelter by fifty per cent means the coming of a greater Hayden.

Chloride.

F. E. Steffy, of Salt Lake, who has just completed a 150-ton reduction plant for the Arizona Butte Mines Co., on Stockton Hill, announced he will install a 500-ton custom mill here.

The Schuylkill has just installed a 90-hp. Western gas engine, a Sullivan 500-cu. ft. compressor, a drill sharpener, two pumps and an electric light plant.

The Distaff has been unwatered and development work begun after a shutdown of several years. The Hercules has also been unwatered and development work is about to begin.

After being closed down for a number of years the Silver Hill property, the oldest in the district, will be started up this week. A. W. Henning, of Los Angeles, is now in camp making necessary arrangements.

Work of unwatering and repairing the Molly-Gibson-Chloride shaft is being pushed. Hoisting machinery is now on the ground.

The Georgia Mining Co. has begun sinking. The next drifting will be done on the 300 level when that point is reached. Good ore has been found on the 100 level.

The Guggenheims have finished sampling the Payroll mine and it is rumored that they will take it over. Also that they will take over the North Georgia property adjoining. They are now unwatering and retimbering the old Elkhart mine here.

Specimen gold ore, an unusual thing in this camp, was found on the Gold Back property. There is much gold here, but it is usually closely associated with the lead and zinc.

A pack train of burros is being used to get a shipment of 250 tons from the Black Jack mine. This shipment is expected to go much higher than \$100 a ton. Ore contains gold, silver, lead, copper and zinc.

Senator Guggenheim, of Colorado, has had men sampling the Golden Hammer mine. Deal seems assured.

The mill of the Arizona-Butte is working perfectly. Samples of the concentrates taken from the bins show a value of 66% lead, \$45 gold and 12 ozs. silver. Splendid ore bodies are being opened up in the mine.

The Hidden Treasure has just completed installation of compressor and air drills; now running a 500-ft. tunnel through granite to open big vein at depth of 500 ft., with 300 ft. yet to drive.

The Keystone made rich find on 300 level, uncovering 8 ft. of high-grade ore. A mill is now being built.

Desert Power & Water Co., who is building a high-tension line into camp, is now within 12 miles of town. Over 200 houses are already wired and electricians busily engaged

in wiring more. Camp has doubled in population in past 60 days.

Rich copper ore has been found in the Weaver district by G. W. Lynch. The same deposit has been opened on adjoining claims by Richings and Southworth; ore runs high in copper and carries good gold content.

The Schenectady is installing a compressor. Boston investors are inspecting the property. Good ore is showing in the shaft.

Jerome.

Additional impetus has been given development work on the Venture Hill and Verde Apex properties since the owning companies entered into an expense sharing agreement and placed mining operations in charge of John S. Riley. The joint plans were drawn up with a view to opening at depth the deposit of native-copper-bearing ore that was recently encountered in the Venture Hill tunnel. This deposit is one of the most promising opened of late in the Jerome field. At a recent meeting of the Venture Hill in Prescott, Ed Shumate succeeded Boas Duncan as president of the company, and will in the future act jointly with John H. Robinson, secretary of the Verde Apex Co., in the financial management of both corporations.

Development of the Ewing and Hooker group is being pushed with two shifts. The group consists of six patented claims, has been held by the original locators (Ewing and Hooker), since 1894, and is surrounded by the Green Monster, Copper Chief and Copper Chief Extension companies. The group is crossed by one of the boldest outcrops in the Jerome field—an iron gossan showing copper at surface. It lies in the Upper Verde contact about 2 miles from Jerome. A tunnel has been driven on the Porous Iron claim of the group 285 ft., and will be continued to crosscut a ledge that lies about 20 ft. in advance of the present face and to a shaft that lies about 100 ft. ahead. This shaft shows ore carrying as high as 15% copper at a depth of 98 ft. Above that point sand carbonates were encountered that assayed \$90 gold. Ninety-four feet from the mouth of the tunnel a body of ore showing iron pyrites and chalcopyrite was encountered. This ore dipped out of the tunnel 49 ft. beyond the point where it was first found and for that distance gave a general average of 2% copper and \$4 gold per ton.

Three shifts are pushing the drift on the 1200 level of the Jerome Victor Extension toward the United Verde's line, and are making fast progress now that the company's water problem has been successfully solved. The objective is the extension in the Victor ground of the bodies of high-grade copper ore that have been followed in No. 3 United Verde workings, well toward Victor Extension boundaries. As the drift is advanced, copper indications are becoming more pronounced. The present showing encourages Supt. Salisbury to believe that copper ore in commercial tonnage will in due course be encountered.

Prescott.

Under the direction of M. N. Andrews a camp will be established on the Union group in the Chaparral country. This decision follows the purchase of the property last week from John S. Jones by D. M. Lacey. St. Louis and Chicago capitalists are interested with Lacey in the venture. The transfer involves approximately \$300,000 on the deferred payment plan. A substantial payment was made at the time of signing the contract and other payments are to be made on Nov. 15, Dec. 15 and Jan. 10. The contract likewise provides for yet other payments as the property is opened and developed. The work will be in charge of Andrews, who interested Lacey in the project.

The customary carload shipment of copper ore went out late in September from the Pittsburg mine on Castle creek. It averaged 15% copper as well as zinc and gold contents. The dump holds a large tonnage of second-grade ore that could be profitably worked by establishing a concentrating plant at the mine.

Chloride.

The Keystone Con. Mining Co. is constructing a concentrating mill of the Fields flotation type, with an initial capacity of 100 tons. In mine development this week a rich ruby silver strike was made, sampling 226 ozs. silver and 1.41 ozs. gold.

CALIFORNIA.

Jackson.

Efforts to resume operations at the South Eureka mine brought the first clash between the striking miners and authorities last week. About 400 armed strikers surrounded the property, drove back deputies and strike breakers, and stopped pumping operations. Sheriff Lucot has asked for assistance from Governor Johnson, stating the situation is beyond his control. It is probable several companies of California militia will arrive here shortly. Most of the strikers are foreigners.

Large numbers of miners have left Amador districts for other fields, but some have returned with the declaration that companies at Grass Valley, Sonora and other camps refused them employment. Leading operators state that fully 1200 of the 1800 men on strike are prepared to return to work on the old scale of wages, and that fully 400 men have left the county since the trouble begun.

The Plymouth Con. is still operating at full capacity near Plymouth, and unwatering of the Old Eureka, at Sutter Creek, continues steadily. Pumpmen have walked out at the Central Eureka, and other companies are facing water problems. Events of the past week indicate the strike will be bitterly contested by both factions.

Marysville.

Arrangements are being made to start work at the Red Ravine and Elk mines in the Indian Ranch district. A patent will first be secured, and subsequently a large amount will be expended on equipment and developments. The group is largely owned by Otto Kipp of Milwaukee, Wis., and Otto Wulwebber of Sheboygan, Mich.

The Pacific Dredging Co. is rapidly transforming the old settlement of Parks Bar into one of the most animated dredging camps in California. Numerous buildings and residences are going up, and the new dredge will soon be ready for operations. Two more boats will be constructed next summer. The camp lies in the Yuba River field, between Marysville and Smartsville. The company continues to explore adjacent territory with drills and prospect pits. The new dredge will operate on territory adjoining the main holdings of the Yuba Con. Gold Fields. The company is controlled by the Yukon Gold Co.

Oroville.

So satisfactory has preliminary dredging of old tailings in this district been that the Natomas Con. has arranged to place another dredge in operation. The ground being reworked was the first to be successfully dredged in California, and the work proves that the old boats failed to clean the bedrock thoroughly and that considerable gold escaped the buckets. It is likely that other companies will arrange to dredge their holdings, as the profitable character of the work has been established.

Pike City.

The owners of the Alaska quartz mine have completed arrangements for the driving of a main working and drainage tunnel. It will be about 6000 ft. long and is expected to intersect the vein system about 600 ft. below the bottom of the shaft. Water has seriously handicapped operations in the Alaska since the shaft gained fair depth, and the tunnel is expected to facilitate this trouble and facilitate economical operations. Eastern people are largely interested. General W. S. Schuyler is president.

Spenceville.

The Spenceville copper mine has been acquired by the Navajo Copper Co. and preparations have been made for work. A good tonnage of excellent ore is exposed and the small smelter will be enlarged and improved. The ore carries some gold. Sinking of the shaft will be started soon and exploration of new ground prosecuted.

Copper Creek.

It is stated here that Manager Elzie of the Valley View Mining Co. is now in San Francisco on business in connection with the raising of funds to develop this property by driving a tunnel at the foot of the mountain.

Miller and Bowen are developing their claims, especially

the Backbone, late assays of which gave 14% copper and \$8.40 gold. They have just reached the hanging wall in a crosscut and may sink on the ore shoot.

On the Copper Gold group, two new ore shoots have lately been opened on the surface, showing strong veins and ore carrying copper and gold. These veins are the same as Miller and Bowen are now developing to the north of this group.

Railroad surveyors are camped within a mile of here and have run their line on the side of the mountain crossing the Copper Gold group and Miller and Bowen ground, all on the east side of the range.

This road connects with the Southern Pacific and Western Pacific roads near Gerlach, Nev.; runs north through Surprise valley to Cedarville and Lake City; then climbs the range on the east side and by a tunnel $1\frac{1}{4}$ miles reaches the west side under Fandango pass; thence down Fandango valley and into Goose Lake valley, passing the foot of the mountain, where High Grade is situated; thence on to Lakeview, Ore., where it will have connections with the Hill and Harriman lines now under construction. This information is from apparently a very reliable source. This road will assist very materially in opening up this mining section and that of High Grade, which is now much handicapped by the extortionate rates.

Forest.

What is believed to be the north extension of the Bald Mountain channel has been intersected in the Bald Mountain Extension. The discovery was made in the Rock Creek tunnel. W. F. Copeland is manager.

Quincy.

The Buckeye-Belmont Co., of Tonopah, has secured control of the Empire Plumas placer mine and is preparing to work it in conjunction with its Chippis Creek Con. group. The channel is about 400 ft. wide and 20 to 40 ft. thick. The tunnel will be enlarged, additional sluices installed, and operations prosecuted on a broad scale. Abundant water is assured.

C. W. Becker and Walter Robinson of Toll Gate have installed some equipment on their placer claims near Hartman's bar, on the middle fork of Feather river. Prospecting will be carried on by the diving system, and it is possible a suction dredge may be installed.

Grass Valley.

A complete pumping and hoisting plant, together with a compressor and machine drills, have arrived at the California mine, about 4 miles below town. Machinery will be installed at once and unwatering of the shaft rushed. The property lies in the Deadman Flat district, and was recently acquired by eastern capitalists headed by King C. Gillette.

Sawyers Bar.

A strong quartz vein which is believed to be the source of the rich placer deposits of this vicinity has been uncovered in the Burro creek Specimen creek section by Holmes and Puttman. The ore body is said to be large and shows much rich quartz. The discovery has stimulated prospecting at several points.

Sutter Creek.

An examination of the Rose mine has been completed by San Francisco engineers and it is reported a deal for the property is pending. The Rose, often known as the Poundstone, has been developed by two shafts and extensive lateral workings, and has yielded much good ore. It is equipped with a 20-stamp mill and excellent mine plant.

The W. J. Loring Co. is busily engaged in reopening the Hardenberg. A new cable has been placed in the shaft and unwatering and retimbering of the shaft is to be pressed energetically. The property is provided with a 20-stamp mill and modern mine equipment and lies in a noted district.

Big Pine.

The Bunker Hill mine, located across the White mountains from Big Pine, has been sold to a group of Whittier people by Arthur Perry. The ore is chiefly valuable for its silver and lead, but considerable high-grade zinc occurs. A large tonnage is exposed underground and the ore on the dumps is estimated to be worth from \$70,000 to \$100,000. Caterpillar engines will be used to move the ore to the Saline Valley tramway, from which point it will be delivered to the

railroad. The tramline is 1800 ft. long and has a vertical drop of 600 ft. It is planned to start heavy shipments immediately. First payment on the purchase price has been made.

COLORADO.

Colorado Springs.

With a surplus in its treasury of \$60,500, which sum is being increased at the rate of \$10,000 monthly, affairs of the Isabella Mines Co. are in an exceptionally good condition, according to announcements made after a meeting of the board of directors. The company's mill is running smoothly and the first clean-up is expected next week. Within a few days the new ore house will be completed, and it is believed that with the mill running capacity good profits will be realized by the company.

The directors of the Mary McKinney Mining Co. have declared a dividend of 1 cent a share, payable Oct. 26, to stockholders of record the 16th. This is the first dividend to be paid by that company since July 25, 1914.

Returns have been received by Alex. Hickman & Co. on the last 2 carload shipments from the Shoo Fly mine on the southwestern slope of Womack hill. Both carloads were of mixed ores, coarse quartz and screenings and brought settlement at close to the same figure. One car of 25 tons was settled for at \$49.60 a ton, and the second brought \$48.80. The second car contained a little better than 26 tons.

Rico.

In the Smuggler drift at the Syndicate mine, some fine lead-zinc-silver ore is being taken out by the Rico Mining Co. Assays run as high as 400 ozs. of silver. The stuff will average close to \$300 per ton. About 4 tons are already sacked, and the vein is showing up strong.

Idaho Springs.

F. B. Hall of New York has taken over the Silver Horn group of 9 claims, situate up Ute creek, owned by L. McLean. The property has about \$20,000 of development work, a 900-ft. tunnel having been driven through the center so that all the claims could be worked from it, and has produced more than \$10,000 in doing the development. It is the intention of Hall to install a new plant of machinery on the property and inaugurate development and thoroughly prospect the property.

Breckenridge.

The two dredging companies sent in three lots of gold to the Denver mint last week valued at \$25,000.

The Wellington Mines Co. paid this month its 12th dividend. This one was for \$200,000, making a total of \$600,000 paid during 1916. The principal product of the company is zinc blende; both crude ore and concentrates are also produced. The two concentration mills on the property are kept running full time on ore from the mine, which is situated on Mineral hill, about $2\frac{1}{2}$ miles easterly from Breckenridge, more than one hundred 25-ton carloads of ore and concentrates were shipped from the property during September. In addition to the usual mine development, the company has started a prospecting shaft on the "fraction" near the west end line of the property. The shaft is now down about 40 ft. and a hoist is being placed on the new shaft. R. M. Henderson is the general manager of the property and Charles Altland, the superintendent.

Telluride.

The Matterhorn management is working a double shift through the lower level of the Butterfly drifting into their veins which lie to the south of the Butterfly property. As the tunnel is not equipped with power, hand work is being done.

Frank Ensign has this fall opened up a big lead of lead ore on a property that he and others own on Mt. Wilson and which he is working at this time. It is one of the few big leads on Wilson. There is said to be about 10 ins. of solid lead.

It is given out that the Standard Chemical Co. will soon begin active work on its properties in the Paradox Valley, and that the company will concentrate the mine product and haul by wagon to Placerville, thence ship east by freight.

IDAHO.

Wallace.

The development of the Vienna-International, situated on Placer creek, about 6 miles from here, is progressing satisfactorily, and unless all signs fail the Vienna-International will prove to be an important lead producer and mark the beginning of greater mining activity in a section that has to a great extent been ignored by capital seeking investment in mines. The property is under bond to F. C. Bailey, of Spokane. The main development consists of two tunnels, the upper, or No. 2, having been driven 635 ft. and intersects both the Vienna and International veins. Drifts have been run east and west on the last named, exposing considerable ore of milling grade. No. 3 tunnel is 90 ft. below No. 2. This has been driven 334 ft. to the Vienna vein, disclosing a good showing of lead-silver ore. From the face a raise has been made to No. 2, all in ore. Drifts east and west have also been run for about 50 ft., showing from 3 to 5 ft. of good milling ore. A shaft has been sunk from this tunnel to a depth of 120 ft. and the vein crosscut showing it to be 25 ft. wide, 3 ft. of which is ore of fair grade and the balance of the ledge strongly mineralized. A drift is now being run west from the bottom of the shaft and the character of the ore is rapidly improving.

Negotiations are pending for the purchase of the holdings of the Portland Mining Co., consisting of the Sitting Bull, Silver Tip, Mule Deer and Red Dragon claims, in the Beaver creek district, by the Sunshine Mining Co., which also is endeavoring to secure the Parrot claim. The Sunshine group consists of 6 claims lying west of the Idora and extending to Beaver creek near the Idora mill. The Sunshine company also holds the Toughnut under bond, which lies to the north and joins the Tuscumbia on the west, and the new company now in process of formation will have holdings extending from the Sunset mine to Beaver creek, with one link missing in the chain, the Tuscumbia. Efforts were made to bring the Tuscumbia into the consolidation, but without success. It is understood that the organization of the new company will soon be completed, when plans for development on a large scale will begin. Some ore has been exposed in the upper tunnel of the Sunshine, but the main development is the tunnel started near Beaver creek, which will cut the Idora vein at a depth of probably 1200 ft. It is expected that this tunnel will cut the vein within the next 40 or 50 ft. This vein is about 400 ft. south of the Toughnut vein, to which a crosscut will no doubt eventually be run from the Sunshine tunnel. A compressor has been ordered by the Sunshine. The foundation is in readiness and the Montana Power line is being extended to the plant. The following officers and directors were elected by the Sunshine Co.: David C. Smith of Missoula, Mont., president; D. L. McGrath of Wallace, Ida., vice-president and manager; Dr. E. G. Ellis of Missoula, treasurer; G. W. Dougherty of Wallace, secretary. These with E. R. Day and James R. McGrath of Wallace and Mrs. Matilda Ellis of Missoula compose the directorate.

Adair.

The Richmond Mining Co., of which Martin Woldson, president of the Spokane Scandinavian-American bank, is president; Charles Heidenreich secretary and general manager, and T. W. McGowan, a Spokane hardware dealer, is treasurer, is now operating the Richmond mine, near here, at a profit, according to Henry M. Lancaster, mining engineer, who states that 6 cars of crude ore were shipped in September. Extensive development had revealed an immense shoot, but the owners were not aware that much of it, regarded as too low grade to mine profitably, was really shipping product, carrying average values of 7.5% copper, more than \$2.50 in gold and a tenth of an ounce of silver, until Lancaster made exhaustive samplings of the body. "More than \$500,000 worth of ore is blocked out above the first level at a depth of about 100 ft.," said Lancaster. "It lies in a shoot having a length of 372 ft. and an average width of 7 ft. Probably as much ore lies above the tunnel level, 260 ft. below. A connection between the tunnel and the shaft will have been made in 30 days, when shipments may be made to Adair, 3 miles distant,

at half the cost for cartage, now \$3 a ton, to Saltese, Mont. We have six 4-horse teams hauling and have contracted for five more. In a few days we will be shipping at the rate of a carload a day. The cost of mining transportation and treatment at Greenwood is about \$15 a ton. The property has been opened by 351 ft. of shaft in three places, 1576 ft. of drifts, 819 ft. of crosscuts and 96 ft. of raises. It is the best little copper mine I know of that has not been shipping."

Burke.

Since building a wagon road and installing a compressor at old Union tunnel the Sherman Development Co. has been engaged in enlarging and straightening the tunnel to permit using a horse in handling the ore cars. This tunnel is 1800 ft. in length and has many curves. This work has been accomplished and the old drift is now going forward. It is 1500 ft. from the face to a point under the ore shoot opened in a crosscut from the Oreano and 500 ft. below, giving a total distance from the surface of 950 ft. Another tunnel was run by the former owners of the Union 500 ft. below, known as the Hidden Treasure, and which will probably be utilized eventually as the main outlet for the mine.

LAKE SUPERIOR.

COPPER.**Houghton.**

Carp Lake is sinking the winze of the old workings. Sinking is also being carried on at shaft No. 16, located a mile west in the same part of the lode. Richard T. Looney of Houghton, who controls the options, with H. T. McKean of Cleveland, president of the Cleveland Paper Co., E. S. Hough of Chicago, manager of the American Cross-Arm Co., and E. C. Jones of Appleton, Wis., who is a large land holder in Ontonagon county, recently visited the mine and inspected its workings.

Franklin during the week ending the 7th averaged 1000 tons daily, consequently its profits will be greater than those of last month, which were about \$30,000. Its yield is now between 13 and 15 lbs. The management is figuring on compounding the stamps and equipping the mill with regrinding machines.

Cherokee, which now has about 110 ft. of heavy copper in its shaft, has been a great and agreeable surprise. The disclosure is so remarkably consistent in its high grades as to give great promise for the lode both on the strike and dip.

Keeweenaw's delay has been in the completion of its rock-house, as carpenters are scarce; but the rope was changed over on to the new shieve wheel the 10th, some hoisting was done the next day, and some rock shipped to the mill the 14th. All three of the lower levels are now in the foot-wall side of the Ashbed lode; the 10th has been proceeding in very good ground ever since it reached that side; the 12th is now in a narrow fault or crossing in broken ground and is almost through it; and the 14th is only just coming in. The latter milled all the rock in the bins the 4th and has been waiting on the rockhouse.

South Lake is maintaining the daily production of 150 tons and will soon raise this figure. The Butler lode is looking better than ever and is now in a particularly rich stretch in the southwestern drift. A rich shoot has been entered for some distance on North Lode No. 1. A recently made survey gives the distance from where the drills are now working on south lode No. 3 to the drift on the same lode at the Lake, along which work is being carried to connect the two mines for ventilation, to be about 800 ft.

Adventure is laying the stringers for the track at No. 3 shaft and will begin to bail out the water and explore the mine's third level, which is the first here. The work will proceed quite fast from now on.

Lake will soon be able to run its hoist and then the work of examining the old workings for deciding on the plan for resuming the exploration can soon be completed.

Ahmeek is doing better than last month and will be able with the 20 cars that are coming from the La Salle weekly to

operate the 7th stamp about 4 days a week. The 8th stamp is practically installed and all the wash is ready with the exception of the jigs, which have not yet come from the Calumet & Hecla shops.

New Arcadian will be in 10 days down to the 1500 level at No. 1 shaft, and will immediately start the 150-ft. crosscut to the New Arcadian lode. The rockhouse at this shaft will require about 25 days more work.

New Baltic is putting up the building for the engine, compressor and boiler, and it will be ready with the machinery by the time the shaft pit is down to the rock; a depth of 25 ft. has been reached so far.

Hancock is increasing its tonnage, both at its own shaft, No. 2, and at Quincy No. 7, the former shipping about 650 tons daily.

Calumet & Hecla has a daily output of 9900 tons. The total tonnage for September for the whole district was less than that of August, as there was one working day less, though the daily rate was slightly higher. The tonnage for October will be a little higher than that of September, as there is a higher daily rate, though the number of working days is the same.

Calumet & Hecla is cutting out at the Red Jacket shaft a large sump or hasin about 950 ft., vertically, measuring, from the surface, so as to catch the water that seeps down through the rock. This work will effect some saving and shows how carefully in this whole district every reasonable effort possible is being made to lower the costs. At this shaft and at the others of the Calumet conglomerate, there are fewer changes in the men than at any other point in the district, but even here a few more could be taken on. As a whole the district is in better condition as to the number of men than for some time past, and the mines that are expanding their work are having more success in getting the additional men needed.

Copper Range is shipping about 3200 tons daily from the Champion, 1300 from the Baltic, and 1200 from the Trimountain. The Trimountain is at the lower levels showing some improvement in the grades of copper.

La Salle is being entered from the 42d level at the Osceola where the ground is much better than in the rest of the present workings at that mine, and it is understood that the same grades are being met with.

Houghton copper is finding, north of the shaft, some fair copper on the 4th level, which was recently opened on the Superior lode. The northern drift at the bottom of the winze, the 12th level, is continuing in good ground but the drifts on the west vein at the same level are meeting with copper only occasionally. The stoping on the 6th level is in good rock and is aiding somewhat towards the expense of the present operations.

IRON.

Ashland.

The Grant & Smith Construction Co. has been awarded the contract to build the third ore dock for the North-Western road here. The road, in making provision for the increase of its ore dock facilities at Ashland, appropriated \$2,000,000 for the purpose, and while the contract figures have not been given out, it is expected that they will be found somewhere in that vicinity. Twenty-seven cars of piling have already arrived at the site of the proposed new dock, and work on the new structure, which is to be rushed, will begin next week.

Duluth.

There are some sales of ore, small lots, at an advance of 50 cts. a ton over prices fixed at the beginning of the year, this for immediate deliveries. Next season, iron ore miners should have at least \$1 per ton over prices received during 1916. The ore producers have made a record shipment, but profits have been very low. Based on what the manufactured end of the steel trade has received prices were beggarly. Steel is still booming, another advance in prices having just been made. Pig iron is also up another notch. If Hughes is elected we expect a great business in iron ore next year. If he isn't then we look for a great slacking up

immediately after the war ends, because in these events we will have free steel coming to us in great quantities and at low prices compared with what we are now receiving for it.

The Florence mine, of the Florence Iron Mining Co., located at Florence, Wis., has closed for the season. Other properties of this company are still in operation at that point. The company had trouble securing boats to take the ore to lower lake ports, and has some ore in stock that will have to be carried over until next season. Freight rates are too high to warrant sending the ore down at this time. The men who worked at the Florence will be given places at other properties of the company.

The mark set for ore shipments from the Lake Superior region to the eastern furnaces this navigation season were 60,000,000 tons, away ahead of any former year, but the belief is growing that it will be much closer to 65,000,000 tons. Never has there been such a demand for iron ore. All furnaces want supplies from Lake Superior, and the mines on the Michigan and Minnesota ranges are endeavoring to meet the want. Ore has been sold to the Atlantic coast furnaces for delivery next spring and it is understood that still further demands from these furnaces are to be met before long, as negotiations are under way for more contracts. The demand from the Atlantic coast is something unusual, for they generally depend upon Cuban, Chilean, New York and Pennsylvania mines for their supplies. Next spring will see the beginning of heavy shipments from this part of the world to the coast. So far as the interior furnaces are concerned, the demand has been getting heavier and heavier as the season has advanced. Stock-piles on the docks at Lake Erie ports have been wiped out. Ore that has been piled up there for years is gone and next spring will see a start with cleaned docks, scarcely anything left in the stock-piles at the furnaces, and with a bigger demand for shipments from there than even this year has enjoyed.

Marquette.

The Cleveland-Cliffs Iron Co. has sold the old Carp River furnace to the Lake Shore Engine Works. The purchase was made for the amount of cast iron it contains. The plant was originally sold to the Cleveland-Cliffs Iron Co. by Charles Schaffer. There are several reasons why the furnace has not been operated for several years past, one being that it has so depreciated in latter years that it would have been necessary to practically reconstruct the plant in order to use it, and another that there was never a chemical plant in connection with the furnace.

The Hoose & Person Construction Co. is employing about 40 men on the stripping contract at the Munro mine, Dickinson county. A considerable territory has been stripped, but the company will not finish the work this fall. The Munro Mining Co. is hopeful of making a considerable shipment of ore to the docks before the close of navigation. A new shaft house is in course of erection and the plant of machinery, including the crusher, is now being overhauled. One of the Hoose & Person Co. steam shovels will be employed in the mining operations. Manager Woodworth is desirous of sending 30,000 tons of ore to the docks, if possible.

Iron Mountain.

The new electrical generating plant at the hoist on Dead river is now turning out 900 kw. of power for the Cleveland-Cliffs Iron Co., and within 10 days it is expected to reach its maximum development of 1000 kw., or approximately 1300 hp. The plant first began the generation of electricity some 10 days ago, and it has been gradually tuned up under direction of O. D. McClure of Ishpeming, the company's mechanical superintendent, until its capacity is now nearly approached. The installation was made under Mr. McClure's direction, the company doing all the work on the plant without resort to contracts. The old dam used in lumbering operations was found in good condition and was utilized in the project with only minor changes. The power house is located 600 ft. below the dam, but in this 600 ft. the water has a fall of 100 ft. For 250 ft. the water is carried in a tunnel, 8 by 8 ft., through solid rock. At the point where it leaves the tunnel it is received by a penstock, 9 ft. in diameter and 250 ft. in length, which carries it to the water wheel.

MISSOURI-KANSAS.

Joplin, Mo.

This week saw another advance in the price of both lead and zinc ores, a feature which distinctly marked the passing of a pessimistic feeling which has existed in the field for some time. Zinc ores brought as high as \$70 for 60% grades, and lead ore reached a maximum of \$80 for 80% grades. At these prices heavy sales were made, and marked depletion of stocks was again noted in practically every camp in the field.

There is a promise of rain which if continued will bring the long needed surface water for the west Joplin group of mines, which depend upon this source for milling ores. Several of this group of mines have tried operations since last week, but met with indifferent success due to the inadequate water supply. While other camps are suffering to a certain extent for the same reason, none have had the extreme limitations forced upon them as have the West Joplin group.

This week notes a decided increase in production, however, in camps at favored points of vantage. There has been sufficient increase in production under the stimulus of better prices to bring the output up to a point between 5000 and 6000 tons weekly.

In addition the resumption of activities of producing character, there is also noted a desire on the part of investors to seek entrance into the field. A number of properties are being examined and there are some prospects of sales being consummated before the winter season sets in.

The St. Paul Mining Co. has undertaken a drill prospecting campaign on a portion of its tract at Granby, operations now being conducted by the Granby Mining & Smelting Co. on the south end of the camp. A drill hole was put down to a depth of 237 ft. and struck ore at 221 ft. with cuttings being found down to 237 ft. This gives a 16-ft. face of zinc blende ore which runs in the neighborhood of 5 to 6%. The St. Paul Co. expects to put down a number of other holes in the development of its Granby property.

The Lucky Star Mining Co., which has a lease on a 40-tract south of Joplin, has opened up a rich run of ore in two shafts, and is now making a good production over hand jigs. The property occurs in soft ground, and ore of a very high grade is being marketed. Last week's ore sales assayed 53%. W. S. McDonald of Joplin is general manager of the property.

Operating under the name of the Big Sandy Mining Co., a group of Joplin men are taking out ore on a new lease of the Gregg land at Tanyard Hollow, southwest of Joplin. In 3 weeks the company put down a shaft to a depth of 35 ft., opened up ore on the 27-ft. level and is still sinking through ore. Those interested are A. J. Poyner, W. E. Jones, O. K. Williams, Chas. Ashley, Bert Lake, B. Roller, and O. Smith.

Preparations are being made for the erection of a new mill on the S. R. & S. Mining Co.'s lease west of Joplin. The ore occurs in soft-ground formation at a depth of 140 ft., and there is a report of considerable ground having been cut at this level. The company has been treating its ores over a custom mill and obtained from 5 to 6% recovery. Those interested in the mine are Homer Seals, Henry Rader, and Homer P. Sewall, all of Joplin. It is expected that a contract will be let on this mill some time this week.

Operating on a 10-acre lease of the Missouri Lead & Zinc Co.'s tract, the Yellowstone Mining Co. has opened up a very rich property and has been turning out from 1 to 2 cars of zinc blende per week. The company is now contemplating erecting a 150-ton mill. Operations have opened up two drifts at the 110-ft. level, which showed a face of ore 50 ft. wide and 25 ft. high. The ore is milling out 17 to 20%. In addition to this developed ore, drill prospecting has showed the occurrence of a lead ore deposit at the 60-ft. level. Those interested in the property are Rob. Kittrell, H. M. Ramsey and John Jarrett, all of Joplin.

A 300-ton mill of the Adirondack Mining Co. on the City of Joplin land is rapidly nearing completion. The mill will be modern and equipped with gas engines. W. H. Roberts of

Joplin is manager and J. H. Gayley, formerly of Pittsburgh, who is now at Carthage, represents eastern investors. Mining is being conducted at the 200-ft. level.

Goodman & Co. have made a rich strike of ore at the 50-ft. level on a 20-acre lease of the Mattes Bros. land west of Joplin. The ore face developed is 6 ft. high and the dirt so far taken out is believed to run from 15 to 25%.

Galena, Kan.

An interesting mining venture in the Galena camp is that being undertaken by a company consisting of C. J. Rhodes of Joplin, E. Davenport of Kansas City, W. H. Pease of Joplin, and Edward Ryan of Galena. They are attempting to re-handle all of the mine sands and gravel which have been washing down stream from the mines at Central City, Galena, and North Empire, which have accumulated along the sand bars just before the stream empties into Spring river. Assays of sand and gravel show values ranging from 2 to 20% zinc and some lead. The company is undertaking the erection of a barge upon which will be placed Diesel engines and sand pumps, which will pump the sands and gravel to a sludge mill erected on the bank of the stream. This will be the first of what might be termed placer or hydraulic mining of zinc ores in the Joplin field.

The Charter Oak Mining Co., operating a lease in Galena Heights, has opened its ground sufficiently to warrant the building of a concentrating plant. The company has been cleaning its ores over hand jigs for several months. The concentrates will run 63% zinc, but the owners believe that with the operation of a mill a much larger tonnage of ore can be treated and profits correspondingly increased.

On a 40-acre tract of the Hurlbut land at Lawton, the Acme Mining Co. is opening up a prospect which promises to become as large a producer as any of the mines so far developed in that camp. Fifteen drill holes have been put down, and some of the cuttings range as high as 10% zinc. A shaft has been put down to the 120 level and the company has been taking out ore and cleaning it over hand jigs. The company expects to build a 200-ton mill and at present are putting down two shafts in order to thoroughly open up the lease.

MONTANA.

Butte.

From present indications stockholders will receive a dividend before the close of the year from the East Butte. The company has recently shipped 44 cars of copper, which are due in New York within the next few days. Upon payment for the shipment, which was sold payable in 60 days, the company will have cash on hand of over \$1,500,000. Just how large a surplus the directors will consider necessary before considering dividend payments is not known, but it seems that the company will soon have an ample amount for its needs. The production for September showed a slight falling off from that of the previous month, but the production for the 9 months of the present year amounted to 13,803,000 lbs., the largest total on record for this period. On its present production, which is at the rate of nearly 21,000,000 lbs. a year, the company is earning, on 25-ct. copper, from \$6 to \$7 a year on its 410,000 shares.

Articles of incorporation have been filed by the Richmond Flats Gold Mining Co. The property is located near Norris and the company office will be in Butte. Directors are: W. A. Reel, J. W. Stiver and W. W. Lamh of Norris, and W. C. Sider and Fred J. Furman of Butte. The capital stock is \$500,000.

Dillon.

Oil operations in the Big Muddy in Sheep creek basin are now going on without interruption and at present the drill is down 700 ft. According to reports from that section the indications for oil were never better and the promoters are very enthusiastic over the outlook. During the past few weeks the oil fields have been visited by several experts.

Hamilton.

The Duluth capitalists who have been associated with James B. Stevens in the Lent mine in the Mineral Hill dis-

trict, have decided to build a 40-ton concentrator near Alta, for the purpose of reducing the copper-silver ores for shipment. There are thousands of tons of this ore on the dump and in the mine and it will be hauled by motor trucks. The high price of metal, together with motor trucks, have solved the problem of operating the mine at a profit. The Duluth men who are associated with Stevens are I. Freinuth, J. B. Sadler and Thomas Klorin.

NEVADA.

Midas.

A new road has been completed from the Lucky Boy mine to the Elko Prince mill, and ore shipments will start shortly. The main vein ranges from 8 to 24 ins. wide and averages around \$30. The 150-ft. shaft is to be deepened to 300 and a crosscut extended to open the Grizzly claim. Eastern people are reported to be negotiating for an interest in the property, which is controlled by R. T. Noble and C. A. Stone.

The Rex mill is running on ore from the Queen mine. Three teams are hauling ore of which there is sufficient for a long run of the plant. Some rich quartz has been extracted recently, and the main ore body continues to show strength.

Bullion to the value of \$90,000 is shipped monthly from the Elko Prince. The June Belle vein is yielding ore of excellent grade, and the company is preparing for more extensive operations on the ledge. Lessees are mining good ore at several points.

Jarbidge.

The Sloss interests of San Francisco, represented locally by George Shoupe, are operating the Long Hike, Starlight, Alpha, and O. K. mines in Bourne gulch. An option has also been taken on the Jarbidge Central group of 9 claims. The Alpha mill is running on good grade ore from the O. K. The Long Hike is apparently developing into a big producer, with the veins persistent and of pronounced strength. A large tonnage of profitable ore has been blocked out and it is reported a large mill will be erected next summer. Rich ore has been intersected in the Starlight, and is thought to be an extension of the Long Hike ledge.

The Bluster Con. and Success mines are being developed by a main tunnel which is planned to open the ore deposits to a depth of 600 ft. The Bluster vein has been opened to a depth of 250 ft. by a crosscut and shows much ore of good milling grade. The company owns an excellent water right and plans building an electric power plant next year. Options have been taken on the Pick & Shovel, Flaxie, and Legitimate properties. All these mines have produced good ore and promise well.

Berlin.

The Alexander group, 6 miles south of Berlin, has been acquired by W. J. Webster and associates. The old mill has been remodeled, and cyaniding and leaching equipment is being installed. The old dumps are said to contain 100,000 tons of ore assaying \$15 to \$25, consisting largely of silver. Plans have been made for extensive work underground.

Round Mountain.

Hydraulic mining ceased several weeks ago at the Round Mountain property, but the management is still maintaining a reduced output by means of scrapers. The richer gravel is scraped into wagons and dumped into the sluices that are still supplied with a fair amount of water. The material is yielding \$2.50 in gold gross. Sluices and flumes are being placed in shape for resumption of extensive hydraulicking as soon as water is available.

Goldfield.

The Silver Pick Co. has moved the Calyx drill to a point westerly of the last hole bored and is again prospecting a wide area of virgin ground. At a point 450 ft. west of the main shaft the drill penetrated three distinct veins, and these will be opened by drifts from the shaft, which is now close to the 1000-ft. point. Exploration of the shale-lattice contact and alaskite-shale zone will begin at an early date.

The Atlanta Co. has started a drift near the center of the

Consolidated vein, recently penetrated by the crosscut from the 1750 level. The ledge at this point is 60 ft. wide and gives low assays in gold and copper. The drift is designed to pick up a rich shoot formerly worked near the 1500 level, while making connections between the Atlanta and Grizzly Bear mines.

Tonopah.

The West End Co. has declared a 5-ct. dividend, payable Oct. 24. It amounts to \$89,545, and makes a total of \$625,970 distributed to stockholders. Retimbering of the old Ohio shaft is proceeding rapidly, and sinking will be resumed at an early date. Most of the ore from the main West End mine is drawn from the 300 and 400 levels. Considerable ore is also coming from the ground disputed by the Jim Butler Co.

Dayton.

A Salt Lake syndicate, consisting of G. T. Hansen, Col. J. F. Cowan, B. Binnard, John Pingree and others, is undertaking the treatment of about 400,000 tons of mill tailings at Dayton, to recover gold, silver and mercury contents. These tailings were deposited by the Virginia City mills 25 to 35 years ago. By long exposure they have become thoroughly oxidized, and will be treated by cyanidation. It is stated that they have a gross value of \$8 per ton, based on present metal prices, the silver content being the most valuable. The quick-silver, originally lost in the amalgamation processes, is to be recovered by mechanical means.

Fairview.

Nevada-Rand Mines Co. has been organized to develop and operate a property, located and partly developed by miners, and situated 30 miles from Nevada Hills, and 15 miles east of Nolan station. Chas. Huber, Tonopah, is president; Chas. Koegel is vice-president and superintendent; C. R. Murdock, Reno, is secretary and consulting engineer. The holdings contain a fissure, in andesite, rhyolite and dacite. The ore produced thus far was rich enough in silver and gold to bear sacking and shipping. Considerable development has been done through shafts from the surface to a depth of 250 ft., showing a vein 30 to 40 ft. wide. At this depth the ore is oxidized, but the plan is to sink 200 ft. deeper to get into sulphide ores. A mill in that locality may be leased to treat the oxidized ores by cyanide. It is claimed the mill ore will average over \$10. The Queen Regent Merger Mines Co. and the Gold Pen Mining Co. are developing and operating on the same ore belt. All these properties have produced close to \$150,000.

Good Springs.

Ingomar mine, situated 22 miles from Good Springs, and 16 miles from Roach station, controlled by S. S. Arentz and W. A. Perkins of Salt Lake, is producing zinc carbonate and lead sulphide ores. The last three shipments of zinc ore, to Bartlesville, sampled 43%. A car of lead ore, sent to Salt Lake smelter, ran 70.8%. The analysis of the zinc ore was as follows: Zinc, 41.22%; lead, 2.8%; iron, 1.6%; silver, 0.5 ozs.; insolubles, 9%. That of the lead ore was: Lead, 70.8%; zinc, 6.8%; sulphur, 9.6%; silver, 2.65 ozs.; iron, 0.6%; insoluble, 1.8%. A quantity of mixed lead-zinc ore has accumulated, which will be separated by hand jigging. The ore is conveyed by gravity from the mine to the loading bins, a distance of 1100 ft., through a metal chute, 11 ins. diameter, placed at an incline of 30°. The ore occurs in two fissures in limestone, 200 ft. apart. Most of the development is confined to one fissure. The mine is opened by an adit level on the vein, with much stoping ground above it. It is possible to get an additional depth of 1000 ft. on the vein by driving another adit from a point farther down the hill.

NEW MEXICO.

Mogollon.

At the Pacific mine the past week a 3½-ft. vein was cut on 600 level and it will be developed both north and south. Headframe and loading bins for the wire rope tramway are about completed.

The new 3-compartment shaft of Mogollon Mines Co. has reached a depth of 950 ft. Ore pockets and sump are being cut and development will be started from both the 800 and

900 levels. This mine has been producing steadily for a number of years, and from a block of ground 2000 ft. long by 700 in height has yielded upwards of \$6,000,000 in gold and silver. This new development will open up virgin ground and will undoubtedly add large ore reserves to the property.

The Socorro Mining & Milling Co. has eliminated concentrating tables in mill and will turn all the product into bullion. The change has effected an increased saving of values. The plant treats about 230 tons of ore daily.

OREGON.

Sumpter.

Active mining operations will be resumed at the Cougar mine, near here, in the next 30 days, according to C. C. Robbins, secretary-treasurer of the United Gold Mining Co., a Spokane corporation, which recently purchased the property from the former owners, among them John Larkin of Spokane, who is heavily interested in the new concern. The old mill is being remodeled and equipped with modern machinery, and a 2½-mile pipe line is being installed to provide water for power and milling purposes. As soon as these betterments are completed production will begin. "The former operators of the property did not make a success because the concentrating system employed was not suited to the ore," said Robbins. "We have had exhaustive tests of different treatments made, and we have discovered that a satisfactory recovery is possible by finer grinding before cyanidization. The former management used cyanide, but did not reduce the ore to sufficiently small mesh to get the desired results. The plant has a capacity of 125 tons, provided by two 5 by 8-ft. tube mills and five 20-ft. cyanide tanks, but this can be expanded to 250 tons by the addition of tube mills and tanks. About \$150,000 had been expended on development and improvement up to the time we bought the property. About 5000 ft. of work had been done on the ledge, blocking out 100,000 tons of ore having a value of more than \$1,000,000. The engineer who supplied these figures took 176 samples and in measuring the total value he eliminated all assay returns above \$20. It has been estimated that 34,000 tons above the first and second levels have an average value of \$14. The cost of stoping and milling is \$3. The shoot is continuous for 1100 ft. and has a back of 390 ft. at its interior extremity. Another \$1,000,000 will be added to the resources by driving a tunnel 100 ft. below the upper block if the ore continues. This tunnel is now at the 500-ft. point."

SOUTH DAKOTA.

Deadwood.

E. S. Shepard, assayer, Deadwood, has for some time been conducting an investigation of ores of the Montezuma and Whizzers property, located between Deadwood and Lead. The veins are not unlike the Homestake in classification of the rocks. Large parallel veins pass through the property. An east blind vein is showing by drill samples some nickel and cobalt—the former in commercial quantities. Another large nearby vein also shows nickel values.

Custer.

Some time ago a tramway was installed from the Two Johns mine to the railroad tracks near Crown Hill, a distance of about 4000 ft. When first placed in operation the cars, which are hauled up to the summit of the tramway by a steel cable, and which descend by gravity, had been moved by a gasoline engine. This method proved too expensive. The Consolidated Power & Light Co. is building a line from its main feed line to the plant of the Two Johns near the railroad tracks at Crown Hill. This line will be completed in a few days; when the wires shall have been strung they will be connected up with the 50-h.p. motor which has been installed in the plant and electricity will hereafter be employed to operate the cars on the tramway. At the present time the Two Johns is hauling about 30 tons of ore daily for delivery to the Trojan milling plant. The new installation will increase this output.

UTAH.

Alta.

The Cottonwood-Atlantis Mining Co. is developing and mining at Atlantis mine, situated at the head of Collins gulch, Little Cottonwood canyon, Alta district. A tunnel was driven in 450 ft. some time ago, and from a point on this tunnel a crosscut is being driven southeast to cut the ore in the well-known thrust contact on which the Cardiff is operating. This contact vein is in limestone, overlain by quartzite. A portion of the property is under lease to miners who will take ore from the quartzite. Ore running high in silver, lead and gold, with some copper, was mined there many years ago. I. A. Clayton, of the Inland Salt Co., Salt Lake, is president of the Atlantis company.

Bingham.

The Bonanza tunnel of the Utah Bingham advanced 37 ft. Total 557 ft. The vein filling, after becoming soft during the past few feet, has become wet and loose, requiring timbering. The vein carries 4 ins. of iron sulphide on the hanging wall. With a little further drifting an upraise is to be made on this iron sulphide. The West Rough & Ready vein has not yet been encountered. The broken condition of the Giant Chief may indicate the approach of the intersection of the Giant Chief and the West Rough & Ready. The Giant Chief main level No. 6 sub-level advanced 32 ft. Total 58 ft. This face has broken into the porphyry foot wall. It carries a little mineral but no ore body. The Giant Chief main level No. 6 raise advanced 28 ft. Total 94 ft. Small spots of ore are being found in the vein. The back shows a large stratum of chert and altered lime and a few tongues of porphyry. This condition is very favorable for ore. The ground, in fact, is ore bearing but no actual ore body has been encountered.

Scranton.

Property of Scranton Mining & Smelting Co., 12 miles south of Eureka, being operated by Scranton Leasing Co., of which J. M. Wade is in charge, is producing 500 tons of ore per month. The larger part of this runs 29 to 35% zinc and 25% iron; the other part runs 20% lead. All this consists of carbonates and oxides. The zinc-iron and lead ores occur in different shoots, and are mined and shipped separately. Most of the operations are carried on through tunnels, drifts, raises and winzes. R. M. Deighton represents the owner company in Salt Lake.

Alta.

Michigan-Utah mine, Alta, is shipping 2 cars per day of ore running \$18 to \$20 per ton, all of which is produced by leasers. The ore samples 12 ozs. silver, 10% lead, 3% copper and 50 cts. gold. All operations are through tunnels and raises. The holdings extend from Alta over the divide to the Big Cottonwood side. The company is extending its Copper Prince tunnel, and is driving a crosscut from the face of this tunnel to intersect several veins. Also, a drift is being run from that tunnel on the line of a contact between limestone and quartzite, to open ore in the lime. N. W. Haire, Salt Lake, is president; A. O. Jacobson is general manager.

Big Cottonwood Con. Mining Co. lately installed a Sullivan single-stage 12x10 air compressor and 50-hp. G. E. motor at its property on south fork of Big Cottonwood canyon, ¼ miles from Cardiff mine. A crosscut has been driven 740 ft. toward the lime-quartzite contact, supposed to be the same as that of Cardiff and others. The crosscut heading is now close to contact, where they expect to find ore. J. F. Dunn is president, with J. P. Waite as secretary and treasurer. Jay Elliott Johnson is manager.

Park City.

It is reported that the Three Kings has struck a body of ore. One story is that the find was made near the surface and the other that it is at a depth of about 500 ft. The report has not been confirmed.

Shipments of crude first-class ore and products from the mills this week totaled 1707 tons, estimated at \$70,000. This is compared with 1578 tons the previous week. There are nine shippers in the list this week, which is a much larger number than usual. The list is as follows: Silver King Coalition.

963,360; Judge Smelting, 891,200; Ontario-Silver, 652,850; Daly West, 330,500; Silver King Con., 205,470; New Quincy, 108,200; Naildriver, 105,320; American Flag, 82,570; Daly, 76,000; total, 3,415,470 lbs.

The Naildriver is getting in shape to do more extensive mining. Everything is reported in good shape now that the pumping has been pretty well accomplished, and operations can be expedited.

Salt Lake.

Stockholders of the King William Mining Co. received notices this week signed by President Blanchard giving outline as to the reorganization. The officers of the new company chosen were as follows: C. H. Blanchard, president; F. G. Morse, vice-president; N. G. Hall, treasurer, and W. A. Wight, secretary. The statement calls for ½ ct. from old stockholders, who will receive share for share.

According to word from Provo, the Blue Bells Mines Co. has been organized to develop the Blue Bell and the Blue Bell Nos. 1, 2 and 3 mining claims in Little Cottonwood mining district, which are made the basis of a capitalization of \$10,000, in shares of the par value of 1 ct. each. Springville is the company's principal place of business. The directors and officers are: George A. Storrs, president; C. A. Daley, vice-president; Fred Dunn, secretary and treasurer; C. L. Daley and A. L. Daley.

Utah stockholders in the Ohio Copper Mining Co. are still unsettled in their minds as to which is the best plan held out to them in the two propositions for reorganization just presented from the east. After the meeting Thursday in this city a wire was sent to both the eastern syndicates. In substance it is that the Utah stockholders, representing 31,000 shares, cannot yet give preference to either plan without giving them further investigation. A Salt Lake man in close touch with the situation estimates that the Ohio stock held in Utah, Montana and Idaho will probably reach 70,000 shares. This is made up mainly in small blocks and up possibly to 2000 shares. This man says: "Personally, I favor the plan of Hubert E. Rogers. It is a 2,000,000 share corporation with 1,300,000 underwritten at \$1 a share. Stockholders will get share for share on payment of \$1 a share. This assumes that the \$750,000 sheriff's sale of the property will be taken care of with this money. The other plan is backed by the International & Intercontinental Mining & Refining Co. It calls for \$2 a share, the stockholders participating in the underwriting. It proposes to require the bondholders to pay off practically all the debts and receive stock in part payment. The present bonded indebtedness of Ohio is \$1,242,000. The floating debts will probably amount to not more than \$60,000. It will be noted that A. Frank, present leaser of the Ohio mine and mill, recently testified that he had paid into the company \$450,000 royalties. I think the New York receivers now must have at least \$600,000 cash on hand. The Frank lease will expire Dec. 1, and I expect the company to be under competent management by that time and ready to step in and take over and operate the property. No doubt the mill will be found in bad shape, but under the Rogers plan all the debts could be cleared and a working capital left of \$300,000 to \$400,000. With this the plant could be placed in first-class condition and the mine should be put on a paying basis. I figure that the Ohio tailing dumps alone make up an asset worth more than \$3,000,000. You know that the saving in the mill has not been much over 45%, which indicates that 55% of the values must be in the tailings."

Eureka.

Shipments of ore from the mines of Tintic in the past week totaled 197 carloads. This is estimated at 9850 tons, valued at \$245,000. It is compared with 175 carloads the week previous. Grand Central is showing a heavy increase in tonnage, equalling this week the Centennial-Eureka. The Chief Con. still holds the lead, with the Dragon following close on its trail.

The shaft at the Eagle & Blue Bell mine is down a distance of about 1950 ft. and sinking will be continued until the 2050 level is reached, when another station will be cut and drifts sent out after the ore. At 1925 ft. a drift was driven in ore for 20 ft. There was no change in that distance and being confident that the ore is making to much greater depth the management decided to put the shaft down at least an-

other 100 ft. before trying to get any further line on the ore. It is practically a cinch that the big ore body, which has been opened in such a splendid manner on the levels above and which was also cut by the main shaft, will be located without difficulty at a depth of 2050 ft., which would give the mine almost unlimited stoping ground.

WASHINGTON.

Spokane.

The Intermountain Mining Co. is placing its property in a condition for operations at increased profit, according to F. H. Walker of Jackson & Walker, who spent a day at the mine recently. Receipts will soon be on a basis of \$23,000 a month, he estimates. "A contract has been closed with the LaCasse Brothers, the operators of a dredge, for the use of their electric power and of two motors during the winter," said Mr. Walker. "A new shoot has been found at depth on a side of the gulch opposite that in which the shaft was sunk and two on the No. 2 level. The shoot across the gulch will have 500 ft. of backs at the point of its intersection. A stope on the No. 2 level has a width of 17 to 20 ft. This body has a copper content of 2½%, but streaks having a width of 1 to 2 ft. contain 10 to 11%. The Hardinge mill has been in operation several weeks. A carload of concentrates is being obtained every fifth day from the jigs and tables and a carload every fifth day from the flotation system. One to two carloads of clean ore are taken from the grizzlies every month. This production should raise the rate of shipments to 12 carloads a month. Concentrates from the jigs and tables have a value of 15% and copper from the flotation system 18%. At \$1800 to \$2000 net to the car the receipts should be about \$23,000 a month. The expenses are about \$6000."

Two placer claims, Baxter and Bradner, located near Sugar Loaf mountain in the Leavenworth mining district, have been sold by Robert Wilson of Tacoma to the Central Products Co. for \$70,000 cash, according to the deed filed.

Fine progress has been made on the Security Copper Co.'s property, according to word from Chewelah. The shaft is now down 495 ft. and will reach the 500 level this week. From this point Manager L. K. Armstrong will run a drift to the ledge, which on the surface is shown to have great width. Work will be commenced at once making the station and sump from which the drift will be run. With the two shafts now employed it is expected that the ledge will be cut by the end of the year.

"Our plant is handling 250 tons of ore a day," said Conrad Wolfe, president of the United Copper Co. "The mill is doing good work and making a good saving, and the company is getting in good financial shape. We also are building an additional mill to treat the tailings. The concrete foundation is completed, the lumber and part of the machinery for it are on the ground and it will be completed in from 4 to 6 weeks. It will cost from \$15,000 to \$20,000."

WISCONSIN-ILLINOIS.

Platteville.

Returns for the week of Oct. 14th of zinc ore to track show it to be the greatest week ever recorded, 197 cars, 7828 tons, all grades being marketed. Buying was heavy; the Mineral Point Zinc Co. receiving 50 cars, 1949 tons; Wisconsin Zinc Co., 37 cars, 1493 tons; Grasselli Chemical Co., 34 cars, 1385 tons; Eagle-Picher Lead Co., all high-grade refinery product, 24 cars, 968 tons; National Separating Co., 17 cars, 715 tons; M. & H. Zinc Co., 13 cars, 496 tons; Illinois Zinc Co., 5 cars, 183 tons; scattering 17 cars, 369 tons. One car of lead ore cleared, 35 tons. Shipments of pyrites came from the National Separators, 277 tons; Mineral Point Zinc Co., 144 tons; Benton Roasters, 120 tons; Linden Zinc Co., 80 tons; Monmouth Zinc Mining Co., 80 tons—about evenly divided between Grasselli Chemical Co., General Chemical Co.

and Commercial Acid Co. Recovery of crude concentrates broke all records with a turnin of 6482 tons net to smelters; mine run direct and finished ore from refineries, 4035 tons. The Mineral Point Zinc Co. shipped 18 cars high-grade ore from separating plants to DePue, 650 tons.

Prices again showed advances especially on the lower-grade ore, the base being raised from \$50 to \$55 on ores down to 50%. Top and standard 60% grades held at \$60 base. Independent operators experienced the best single week thus far this year, 70 cars of ore coming from mines many of which have been denied a market for months.

Benton.

Reports for week of 14th continue at the rate steadily maintained, 79 cars of concentrates being delivered to track for an aggregate of 6,432,000 lbs. Frontier interests marketed 13 cars, 548 tons; Vinegar Hill Mining Co., from the Blackstone, Martin and Kittoe mines to Cuba, 10 cars, 420 tons; Fields-Thompson and Crawhall mines 10 cars, 385 tons; Wisconsin Zinc Co. to separating plants 16 cars, 645 tons; Penna-Benton mine to Mineral Point 8 cars, 330 tons; Wilkinson, Indian Mound and Sally Mining Co. to separating plants, each 2 cars, 240 tons total; Grand View Mining Co., a new producer to Linden Zinc Co., 35 tons. The Eagle-Picher Lead Co., high-grade separator ore from the Skinner plant of the Wisconsin Zinc Co., 15 cars, all to Collinsville, 613 tons. Several new producers recently developed are ready to contribute concentrates and will be reckoned with in shipments within the next 2 weeks. It is contended by expert mining men familiar with conditions in this district that shipments of 100 cars of crude concentrates will be made weekly in the near future.

Highland.

Five cars of carbonate zinc ore were shipped from here last week, all from the mines of the New Jersey Zinc Co. The Red Jacket mine idle several years figures in the late returns.

Linden.

In shipments last week the Linden Zinc Co. ore refiners sent 4 cars high-grade ore to smelters, 160 tons; H. Lewis, from locals in mixed lots to Collinsville, 2 cars, 72 tons; Milwaukee Linden to refinery, 2 cars, 92 tons; Stoner Bros. to Mineral Point, 30 tons; Ross Bros. 30 tons.

Spring Hill Mining Co., Chas. Singer, manager, has its main hoisting shaft down to ore, and a new mill ready. Drilling operations continue for Optimo No. 3 with splendid results. The main pitch has been struck and heavy production is assured. On the Optimo No. 2 a connection has been struck between two runs of zinc ore that will guarantee 2 years' production. Drills continue with success on the lease cuttings assaying 15 to 20% zinc.

Montfort.

The O. P. David reported out 1 car high-grade ore to LaSalle last week, 44 tons.

Mifflin.

Reports covering 2 weeks' returns from the Coker mines made last week show deliveries of 17 cars of zinc ore to Mineral Point, 687 tons; Peacock Mining Co. shipped to Grasselli Chemical Co., a contract with American Metals Co. having expired recently. Lucky Six continues shipments under contract, B & M. to Benton Roasters, 2 cars, 54 tons, and 1 car high-grade to Eagle-Picher Co., 43 tons; Biddick mine to Benton Roasters, 5 cars, 202 tons.

Mineral Point.

From the Mineral Point Zinc Works, one 25-ton tank of commercial sulphuric acid is being shipped each 24 hours. The oxide department is running on triple schedule, with 300 men, and shipments of finished product are made constantly. A strike among Italian laborers was promptly put down and 25 were discharged. Locals operating on the Mitchell land shipped 1 car last week, 32 tons zinc ore.

Cuba City.

Shipments of high-grade ore from the National Separating Works last week were made to Granby Con., 6 cars, 211 tons; Illinois Zinc Co., 4 cars, 143 tons; Standard-Metals Co. shipped 1 car low-grade ore to Wisconsin Zinc Co., 44

tons; Linden Zinc Co., operating the Campbell plant, 1 car 60% ore to LaSalle, 40 tons.

Hazel Green.

Reports for week of 7th were included with returns for week of 14th, showing shipments of 27 cars of zinc concentrates to separating plants in the field, and to Grasselli Chemical Co. under contract. The Maranoff Mining Co. figures for the first time with a car of ore shipped to Galena, 39 tons. Monmouth Zinc Co., also a new producer, resumes shipping after installing additional pumping machinery. Shullsburg made its regular report to Winskill, sending 4 cars to track, 176 tons. From the Potosi district came report of 1 car of high-grade ore from the Wilson mine to LaSalle, 34 tons. Three new power and milling plants will come into operation in the Potosi district before the end of the year.

Galena.

Galena mines are showing better on shipments, the Graham mine among new producers, sending 2 cars to Cuba, 85 tons; Hellman Mining Co., a new outfit, 2 cars to Grasselli Chemical Co., 80 tons; Wisconsin Zinc Co. from the Joplin Separating Works to LaSalle, 5 cars, 179 tons. Galena Refinery Co. has not reported in 2 weeks. Black-Jack shipped 4 cars mine run to Mineral Point, 180 tons; Federal to Wisconsin Zinc Co., 2 cars, 80 tons.

WYOMING.

Holmes.

Manager Dorchester Mapes of the Rambler Copper & Platinum Co., in a recent report states: "We have exposed our high-grade ore vein on the upper levels west of old workings, and are drifting (with machine drills) to cut the vein on the third (145-ft.) level. We are now mining about 3 tons of high-grade ore per day and already have a car load in the bins. At present we are taking out ore through the old works, which were in bad shape from caving, but we are cleaning up and retimbering this ground, and Supt. McMurray is confident we can soon be shipping 3 or more cars of high-grade per month. We have arranged to put on two 6-horse teams, with trailers, and this will take care of at least 7 tons per day. We are developing plans for improvements in our milling methods, which I am confident will enable us to handle our large bodies of lower-grade ores at a good profit. I have instituted a simple system of accounts and records which will enable me to know just how we stand, what we are doing every day, and what every part of the work is costing. The high-grade ore should sell for \$5000 or more per carload. We begin hauling high-grade for shipment this week. The mine is now on a paying basis, even calculating only the copper values in the ore we are hoisting daily."

Lander.

The Wyoming Petroleum Co. has received lately 9 cars of machinery and storage tanks and has another car on the way. Manager I. E. Segur is placing this machinery and tanks on the reservation lease held by his company 9 miles north of Lander in what is known locally as the reservation light oil fields. In the shipment besides the storage tanks were an air compressor and a complete electric light plant. The compressor will be used in erecting the storage tanks. The company has six producing wells and will increase the number to 20 under its present plans. Two more wells are nearly finished and the rigs will be kept at work until the expected number is completed. No statement has been made as to the present production by the management but it runs into several hundred barrels a day. The oil is the best grade light oil so far found in Wyoming. At present owing to a lack of storage the producing wells are not pumped to their full capacity. The company has installed a skimming plant and has been making all the gasoline used by it in its engines. It has not been able to secure the necessary steel barrels to market the surplus. As soon as the storage tanks are completed and the necessary barrels secured it will enter the local field as a wholesaler and supply many retail customers from Lander. The work of completing the storage and drilling the wells planned on will take several weeks.

CANADA.

BRITISH COLUMBIA.

Ainsworth.

The Leo Mining Co., capitalized for 1,000,000 shares at 5 cts. each, of which 200,000 shares are to be held in the treasury, has been organized in Spokane to take over and continue development of a group of claims near here. The officers are Thomas Hooker, president, and G. W. Roche, secretary-treasurer. These, with Walter G. Merryweather, W. S. McCrea and Samuel Hanauer compose the directorate. There are two claims in the property and in addition it has a perpetual right to use the long tunnel of the Highlander property adjoining, from which a drift has been run into Leo ground. It is expected that a continuation of this drift for an additional 100 or 200 ft. will reach the ore body at a depth of 1000 ft. North of the Leo property is the Banker mine, being worked by the Consolidated Mining & Smelter Co. On the Highlander, adjoining on the south, \$200,000 worth of work has been done. Other highly developed properties lie on the south and west.

Sandon.

The new 100-ton mill being built by the Surprise and Ivanhoe companies jointly on the site near Sandon, of the old Ivanhoe plant, which was destroyed by fire while treating Lucky Jim ore, will be in operation in a few weeks. The Ivanhoe tramway has been rebuilt and W. H. Yawkey of New York has resumed the development of that property, which is now in shape to resume production at any time. The ore bodies in the Surprise mine are unquestionably the largest and cleanest in the Sloean district. They are opened to a depth of 1200 ft. below the apex of the vein in Surprise basin. The mine is managed by Alexander Smith, who has been financed entire for 20 years by Congressman Charles Kent of California. The mine now contains vast ore reserves and netted \$180,000 last year.

The Canadian group, adjoining the Ivanhoe, has been reopened and Bruce White has just let a contract to haul 100 tons of silver-lead ore from the Noonday mine at Cody to the railroad at Sandon. The Noble Five is working 3000 ft. below the apex of the Last Chance mine and is taking out a good grade of mixed lead and zinc ore.

Vancouver.

Despite the advance in wages and the increased price of material and supplies, incident to the European war, the Granby Con. Mining, Smelting & Power Co., with mines in different parts of British Columbia and Alaska and smelters at Anyox and Grand Forks, reports net earnings of \$3,819,295 during the fiscal year ended June 30, 1916, as compared with \$1,070,140 for the previous 12 months. Dividends amounting to \$899,911 were paid during the year, and the total surplus at the end of the period was \$6,587,471, as against \$3,668,086 in 1915. This establishes a new high record of earnings and production for the corporation, but it is predicted that the current fiscal year will witness greater accomplishments in this line, the result of increased production and better average prices for metals. During the year 1,807,251 dry tons of ore were smelted from which were recovered 42,198,083 lbs. of copper, 487,845 ozs. of silver and 44,848 ozs. gold. In the previous year 1,098,020 dry tons of ore were smelted, the recoveries being 26,638,912 lbs. copper, 377,881 ozs. silver and 31,388 ozs. gold. The ore reserves of the various mines comprise 9,947,000 tons of 2 to 2½% copper, 3,718,000 tons of 1 to 1½% copper, and 9,491,000 tons of less than 1% copper, a total of 23,156,000 tons. The development work at Phoenix did not replace with new ore the amount shipped from the mine during the year by 721,400 tons, while at Anyox the new found ore exceeded that which was shipped during the year by 182,833 tons. During the year the Anyox plant treated 822,919 tons of ore, yielding 29,562,177 lbs. copper. Tons of charge treated, exclusive of coke, were 1,103,825. There were sent to Grand Forks for conversion 21,428 tons of matte, averaging 14% copper. The ore mined and shipped to the smelter from the Hidden Creek mine during the year amounted to 725,821 dry tons, bring the total shipments to date to 1,270,484 tons. Dr. William H. Nichols, president of the company, in his report to the stockholders says that the output at

Anyox was unfavorably affected both as to volume and cost by the serious curtailment of water power due to an unusual winter. The danger of a possible recurrence of this difficulty will be obviated by the installation of an auxiliary steam power plant, which is nearing completion. "As affecting the question of costs," he says, "allusion might also be made to the high cost of labor and supplies prevailing throughout the year and it is extremely gratifying to note that in face of these conditions the cost of blister copper at Anyox for the year was 8.54, as against 10.09 for the previous year, indicating that considerable progress will yet be made in the line of further reduction of cost. The assessment for the purpose of war tax is in process of adjustment and it appears to be the policy of the Canadian government to avoid making the tax unduly burdensome."

ONTARIO.

Cobalt.

Although not so great as the months of early summer, Nipissing's September production increased greatly over August. During the month the company mined ore of an estimated value of \$236,873, and shipped bullion from Nipissing and Customs ores of an estimated net value of \$413,753. Total for 9 months, \$1,995,013. Results from development appear to have been of a gratifying nature on the whole.

Dome Lake's mill, enlarged from 60 to 200 tons, was expected to be running again at the first of the month, after being shut down since August. Delays in getting shipments on minor parts have held it up, however, and while the mill may resume treatment of ore this week, it is probable that it will be another week at least. In the meantime development work has been pushed, and when the mill does start, production may in a small measure be overtaken by the higher quality ore that has been blocked out lately on the lower levels.

Shortage of material and labor are given as the reasons for abandoning plans made for the construction, before winter, of mill foundations on West Dome. Treatment of ore is set back, at the least, by 5 or 6 months. The proposed new shaft will not be started this year. Orders for equipment for the new shaft, and other machinery for the mine, have been either canceled, where given, or not given at all, for the reason, it is stated, that without lumber no protection from the weather for the machinery could be erected. Opening up of ore is proceeding steadily. From Nos. 1 and 2 veins ore that assays up to \$12 is being taken in drifts at the 300 level, and dumped. Ore taken out in development and dumped is averaging around \$7. While the two new drill holes have not yet reached the high-grade ore system, one diamond drill has struck 17 ft. of low-grade that will average \$5, on the 500 level.

The official report of Hollinger Con. Gold Mines for the 4 weeks ending Sept. 8 shows an increase in tonnage and decrease in grade over the previous 4-week period. Running 90.4% of the possible time, in the 4 weeks 50,177 tons of an average value of \$8.59 were treated. In the previous 4 weeks, ending Aug. 11, tonnage was 43,355 of an average value of \$9.61. Milling costs came down from \$1.053 a ton in August to \$0.927 a ton in the September statement. The tonnage treated was at the rate of 1792 a day. The 200 level provided almost half the ore hoisted. Gross profits for the period were still below dividend requirements. Gross profits for the period ending Sept. 8 amounted to \$221,543.30.

The recent find at the Miller Lake O'Brien continues to show an enormous body of ore in every direction. The find, which is seemingly a solid body of ore, has a width of over 2 ft. and seems to carry its size so far as it has been drifted upon. The winze was put in over 30 ft. which showed ore all the way. Afterwards sinking was done to the same extent and a drift was driven along the body of ore for about 50 ft. The manager is now sinking a winze for that distance. Men working in the mine who have had years of experience in Cobalt, say that there has never been anything to compare with the O'Brien strike. There is no reason to doubt that the working of other properties in the Montreal River section may develop into mines as the O'Brien was not much better looking on the surface than hundreds of other claims in the district.

World's Index of Current Literature

A Weekly Classified Index to Current Periodical and other Literature, Appearing the World Over Relative to Mining, Mining Engineering, Metallurgy and Related Industries, in Four Parts.

Part 1. *Geology*—(a) Geology; (b) Ore Genesis; (c) Mineralogy.

Part 2. *Ores and Metals*—(a) Metals and Metal Ores; (b) Non-Metals.

Part 3. *Technology*—(a) Mines and Mining; (b) Mill and Milling; (c) Chemistry and Assaying; (d) Metallurgy; (e) Power and Machinery.

Part 4. *General Miscellany* (including Testing, Metallography, Waste, Law, Legislation, Taxation, Conservation, Government Ownership, History, Mining Schools and Societies, Financial, etc.)

Articles mentioned will be supplied to subscribers of *Mining and Engineering World* and others at the prices quoted. Two-cent stamps will be received for amounts under

\$1. Subscribers will be allowed a discount of 5 cts. if the price of the article exceeds 50 cts. The entries show:

(1) The author of the article.

(2) A dash if the name is not apparent.

(3) The title, in italics, of the article or book. Titles in foreign languages are ordinarily followed by a translation or explanation in English.

(4) When the original title is insufficient a brief amplification is added. This addition is in brackets.

(5) The journal in which the article appeared; also the date of issue, and the page on which the article begins.

(6) Number of pages. Illustrated articles are indicated by an asterisk (*).

(7) The price.

I. GEOLOGY

GEOLOGY AND MINERALOGY

Geology

Blackwelder, Eliot.—*The Geologic Role of Phosphorus*. [Treats on the action of phosphorus in solution with respect to the formation of minerals and other substances in a general way].—*American Jnl. of Sci.* Oct. 1916; p 285; pp 14*; 60c.

Emery, Wilson B.—*The Igneous Geology of Carrizo Mountain, Arizona*. [Published by permission of the U. S. G. S., giving the petrology and general nature of the rock as a formation].—*American Jnl. of Sci.* Oct. 1916; p 349; pp 15*; 60c.

Jessup, Douglas W.—*The Lakeview Mine, Utah*. [On the geology of the deposits, methods of operation and other general description].—*E. & M. J.* Sept. 30 1916; p 573; pp 374*; 25c.

Roesler, Max.—*Geology of the Iron-Ore Deposits of the Firmeza District, Oriente Province, Cuba*. [A very complete description of the geology, mineralogy and genesis of the ore bodies and formation related thereto].—*Bull. A. I. M. E.* Oct. 1916; p 1789; pp 51*; 35c.

Singewald, Joseph E.; Miller, Benjamin L.—*Prominent Mines of Junin, Peru*. [Three mines in the same district are described as regards their ore deposits. One is vanadium, one bismuth and the last silver].—*E. & M. J.* Sept. 30 1916; p 583; pp 474*; 25c.

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*The Manganese Ores of the Lafayette District, Minas Geraes, Brazil*. [Separate descriptions on different districts and mines, also the nature of the ore and geology].—*Bull. A. I. M. E.* Oct. 1916; p 1745; pp 18*; 35c.

Scott, Herbert K.—*Manganese Ores of the Bukovina, Austria*. [A concise but complete description of the country, the ores, geology, methods of handling and preparing and costs of the same].—*Iron & Steel Inst. Adv. Copy* 5; pp 20*; 50c.

Wolff, J. F.—*Recent Geologic Developments on the Mesabi Iron Range, Minnesota*. [A complete geological review of recent findings which tend to correlate

the formation and ore bodies].—*Bull. A. I. M. E.* Oct. 1916; p 1763; pp 25*; 35c.

Ore Genesis

Blackwelder, Eliot.—*The Geologic Role of Phosphorus*. [Treats on the action of phosphorus in solution with respect to the formation of minerals and other substances in a general way].—*American Jnl. of Sci.* Oct. 1916; p 285; pp 14*; 60c.

Knight, Cyril W.—*Geological Relations of Sudbury Nickel Ores*. [Reviews the nature of the deposits and geology of the related formation. The whole is in the form of discussion].—*E. & M. J.* Sept. 23 1916; pp 174*; 25c.

Roesler, Max.—*Geology of the Iron-Ore Deposits of the Firmeza District, Oriente Province, Cuba*. [A very complete description of the geology, mineralogy and genesis of the ore bodies and formation related thereto].—*Bull. A. I. M. E.* Oct. 1916; p 1789; pp 51*; 35c.

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*The Manganese Ores of the Lafayette District, Minas Geraes, Brazil*. [Separate descriptions on different districts and mines, also the nature of the ore and geology].—*Bull. A. I. M. E.* Oct. 1916; p 1745; pp 18*; 35c.

Mineralogy and Petrography

Blackwelder, Eliot.—*The Geologic Role of Phosphorus*. [Treats on the action of phosphorus in solution with respect to the formation of minerals and other substances in a general way].—*American Jnl. of Sci.* Oct. 1916; p 285; pp 14*; 60c.

Emery, Wilson B.—*The Igneous Geology of Carrizo Mountain, Arizona*. [Published by permission of the U. S. G. S., giving the petrology and general nature of the rock as a formation].—*American Jnl. of Sci.* Oct. 1916; p 349; pp 15*; 60c.

Larsen, S. Esper; Steiger, George.—*Sulphatic Cancrinite from Colorado*. [This paper is published by permission of the U. S. G. S. The mineral is principally a sodium aluminum silicate].—*American Jnl. of Sci.* Oct. 1916; p 332; pp 274*; 60c.

Roesler, Max.—*Geology of the Iron-Ore Deposits of the Firmeza District, Oriente Province, Cuba*. [A very complete description of the geology, mineralogy and genesis of the ore bodies and

formation related thereto].—*Bull. A. I. M. E.* Oct. 1916; p 1789; pp 51*; 35c.

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*The Manganese Ores of the Lafayette District, Minas Geraes, Brazil*. [Separate descriptions on different districts and mines, also the nature of the ore and geology].—*Bull. A. I. M. E.* Oct. 1916; p 1745; pp 18*; 35c.

II. ORES AND METALS

(I) METALS AND ORES

Chromium

Van Name, R. G.; Hill, D. U.—*On the Rates of Solution of Metals in Ferric Salts and in Chromic Acid*. [A discussion and description of experimental work. The nature of the different experiments and results obtained are given].—*American Jnl. of Sci.* Oct. 1916; p 301; pp 3174*; 60c.

—*Quebec Mining Industry—A Review for the First Half of 1916*. [Brief accounts of operations at various properties].—*Canadian Mg. Inst. Bull.* Sept. 1916; p 796; pp 4; 50c.

Copper

Clayton, C. Y.—*Experiments from the Flotation Laboratory*. [Considerable of the text has to do with the nature of different oils. Description of laboratory flotation machines and tests made on different ores are also given].—*Mo. School of Mines Bull.* Aug. 1916; pp 40*.

Gahl, Rudolph.—*History of the Flotation Process at Inspiration, Arizona*. [A paper read before the A. I. M. E., dealing in detail with the subject and equipment used].—*Met. & Chem. Engg.* Oct. 1 1916; p 393; pp 1274*; 35c.

Rawdon, Henry S.—*Notes on the Occurrence and Significance of Twinned Crystals in Electrolytic Copper*. [A paper read before the American Inst. of Metals].—*Met. & Chem. Engg.* Oct. 1 1916; p 406; pp 3*; 35c.

Rickard, T. A.—*J. Parke Channing and Copper Mining*. [A bibliography of Channing's life with respect to the mining industry, principally iron and copper, in this country].—*M. & S. P.* Sept. 30 1916; p 487; pp 12*; 20c.

Stead, J. E.—*Influence of Some Elements on the Mechanical Properties of Steel*. [Gives the results of tests made on steels containing small amounts of other metals, as copper, tin, silicon, phosphorus, sulphur, etc.].—Iron & Steel Inst. Adv. Copy; pp 91*; 50c.

Stead, J. E.—*Notes on Nickel Steel Scale and on the Reduction of Solid Nickel and Copper Oxides by Solid Iron*. [Gives the method of procedure and results obtained in experimental work].—Iron & Steel Inst. Adv. Copy 7A; pp 9*; 50c.

Gold Fields and Mining

Clevenger, G. H.—*Electrolytic Precipitation from Cyanide Solutions*. [A paper read before the American Electrochemical Soc.].—E. & M. J. Sept. 30 1916; p 579; pp 3½*; 25c.

Hillen, A. G.—*Review of Conditions in the Eureka Mining District, Nevada*. [A general review of operations and conditions, both past and present].—Mg. World Sept. 30 1916; p 571; pp 1*; 10c.

Purinton, C. W.; Smith, R. E.—*Winter Sluicing at the Lenskoi Gold Mines, Siberia*. [Describes the methods and plant used for handling the frozen gravel by thawing and treating at once. Mining, construction and other operating costs are given].—Mg. Mag. Sept. 1916; p 143; pp 9*; 50c.

Gold Milling, Metallurgy, Etc.

See Mill and Milling, Metallurgy, Chemistry, Assaying, Etc.

Iron Ores and Mining

Rickard, T. A.—*J. Parke Channing and Copper Mining*. [A bibliography of Channing's life with respect to the mining industry, principally iron and copper, in this country].—M. & S. P. Sept. 30 1916; p 487; pp 12*; 20c.

Roesler, Max.—*Geology of the Iron-Ore Deposits of the Firmeza District, Oriente Province, Cuba*. [A very complete description of the geology; mineralogy and genesis of the ore bodies and formation related thereto].—Bull. A. I. M. E. Oct. 1916; p 1789; pp 51*; 35c.

Wolff, J. F.—*Recent Geologic Developments on the Mesabi Iron Range, Minnesota*. [A complete geological review of recent findings which tend to correlate the formation and ore bodies].—Bull. A. I. M. E. Oct. 1916; p 1763; pp 25*; 35c.

Iron and Steel

Brearley, A. W.—*Some Properties of Ingots*. [A metallographic review of the peculiarities of ingots made under varying conditions. Reproductions of the structure of the steel are shown].—Iron & Steel Inst. Adv. Copy 1; pp 31*; 50c.

Campbell, Edward D.—*The Influence of Heat Treatment on the Thermo-Electric Properties and Specific Resistance of Carbon Steels*. [The results and nature of the tests are described and 8 curves are reproduced showing the results of these and other tests].—Iron & Steel Inst. Adv. Copy 2; pp 18*; 50c.

Hayward, Carle R.—*The Effect of Sulphur on Low-Carbon Steel*. [A review of metallographic tests giving both the structure and change in physical properties due to the presence of sulphur].—Bull. A. I. M. E. Oct. 1916; p 1841; pp 10*; 35c.

Kilby, J. N.—*Steel Ingot Defects*. [The principles of things affecting acid and basic openhearth and Bessemer steel. Various pieces of equipment and methods are also described].—Iron & Steel Inst. Adv. Copy 4; pp 12*; 50c.

Stead, J. E.—*Influence of Some Elements on the Mechanical Properties of Steel*. [Gives the results of tests made on steels containing small amounts of other metals, as copper, tin, silicon, phosphorus, sulphur, etc.].—Iron & Steel Inst. Adv. Copy; pp 91*; 50c.

Stead, J. E.—*Notes on the Effect of Blast-Furnace Gases on Wrought Iron*. [Tests of various kinds were made to determine this effect].—Iron & Steel Inst. Adv. Copy 7C; pp 7*; 50c.

Stead, J. E.—*Notes on Nickel Steel Scale and on the Reduction of Solid Nickel and Copper Oxides by Solid Iron*. [Gives the method of procedure and results obtained in experimental work].—Iron & Steel Inst. Adv. Copy 7A; pp 9*; 50c.

Van Name, R. G.; Hill, D. U.—*On the Rates of Solution of Metals in Ferric Salts and in Chromic Acid*. [A discussion and description of experimental work. The nature of the different experiments and results obtained are given].—American Jnl. of Sci. Oct. 1916; p 301; pp 3½*; 60c.

Iron and Steel: Foundry and Furnace Practice

Kilby, J. N.—*Steel Ingot Defects*. [The principles of things affecting acid and basic openhearth and Bessemer steel. Various pieces of equipment and methods are also described].—Iron & Steel Inst. Adv. Copy 4; pp 12*; 50c.

Stead, J. E.—*Notes on the Effect of Blast-Furnace Gases on Wrought Iron*. [Tests of various kinds were made to determine this effect].—Iron & Steel Inst. Adv. Copy 7C; pp 7*; 50c.

Lead

Clayton, C. Y.—*Experiments from the Flotation Laboratory*. [Considerable of the text has to do with the nature of different oils. Description of laboratory flotation machines and tests made on different ores are also given].—Mo. School of Mines Bull. Aug. 1916; pp 40*.

Hillen, A. G.—*Review of Conditions in the Eureka Mining District, Nevada*. [A general review of operations and conditions both past and present].—Mg. World Sept. 30 1916; p 571; pp 4*; 10c.

Scott, W. A.—*Operations in the Tintic District, Utah*. [Describes the district and its operations in general, and then gives separate descriptions of the operations and methods of some of the companies].—Mg. World Sept. 30 1916; p 583; pp 1½; 10c.

Sims, Clarence E.; Ralston, Oliver C.—*The Electrolytic Recovery of Lead from Brine Leaches*. [A paper read before the American Electrochemical Soc.].—Met. & Chem. Engg. Oct. 1 1916; p 410; pp 4*; 35c.

Manganese

Scott, Herbert K.—*Manganese Ores of the Bukovina, Austria*. [A concise but complete description of the country, the ores, geology, methods of handling and preparing and costs of the same].—Iron & Steel Inst. Adv. Copy 5; pp 20*; 50c.

Stead, J. E.—*Influence of Some Elements on the Mechanical Properties of Steel*. [Gives the results of tests made on steels containing small amounts of other metals, as copper, tin, silicon, phosphorus, sulphur, etc.].—Iron & Steel Inst. Adv. Copy; pp 91*; 50c.

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*The Manganese Ores of the Lafayette District, Minas Gerais, Brazil*. [Separate descriptions on different dis-

tricts and mines, also the nature of the ore and geology].—Bull. A. I. M. E. Oct. 1916; p 1745; pp 18*; 35c.

Silver

Hillen, A. G.—*Review of Conditions in the Eureka Mining District, Nevada*. [A general review of operations and conditions, both past and present].—Mg. World Sept. 30 1916; p 571; pp 4*; 10c.

Scott, W. A.—*Operations in the Tintic District, Utah*. [Describes the district and its operations in general, and then gives separate descriptions of the operations and methods of some of the companies].—Mg. World Sept. 30 1916; p 583; pp 1½; 10c.

Singewald, Joseph E.; Miller, Benjamin L.—*Prominent Mines of Junin, Peru*. [Three mines in the same district are described as regards their ore deposits. One is vanadium, one bismuth and the last silver].—E. & M. J. Sept. 30 1916; p 583; pp 4¼*; 25c.

Silver Milling, Metallurgy, Etc.

See Mill and Milling, Metallurgy, Chemistry, Assaying, Etc.

Tin

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*Silver-Tin Mining in Bolivia*. [Old stope filling is being taken out, chloridized, leached and then concentrated for the tin residue].—E. & M. J. Sept. 23 1916; p 533; pp 3*; 25c.

Stead, J. E.—*Influence of Some Elements on the Mechanical Properties of Steel*. [Gives the results of tests made on steels containing small amounts of other metals, as copper, tin, silicon, phosphorus, sulphur, etc.].—Iron & Steel Inst. Adv. Copy; pp 91*; 50c.

Vanadium

Fischer, Sigfried, Jr.—*Contributions to the Knowledge of the Electrolysis Aqueous Solution of Vanadium Salts*. [Gives the results of previous investigations showing the behavior of vanadium and its salts under various conditions, especially in solution as an electrolyte].—American Electrochem. Soc. Adv. Paper 9; p 119; pp 45*; 35c.

Singewald, Joseph E.; Miller, Benjamin L.—*Prominent Mines of Junin, Peru*. [Three mines in the same district are described as regards their ore deposits. One is vanadium, one bismuth and the last silver].—E. & M. J. Sept. 30 1916; p 583; pp 4¼*; 25c.

Zinc

Clayton, C. Y.—*Experiments from the Flotation Laboratory*. [Considerable of the text has to do with the nature of different oils. Description of laboratory flotation machines and tests made on different ores are also given].—Mo. School of Mines Bull. Aug. 1916; pp 40*.

Jessup, Douglas W.—*The Lakeview Mine, Utah*. [On the geology of the deposits, methods of operation and other general description].—E. & M. J. Sept. 30 1916; p 573; pp 3¾*; 25c.

Miscellaneous Metals and Ores

Blackwelder, Eliot.—*The Geologic Role of Phosphorus*. [Treats on the action of phosphorus in solution with respect to the formation of minerals and other substances in a general way].—American Jnl. of Sci. Oct. 1916; p 285; pp 14*; 60c.

Stead, J. E.—*Influence of Some Elements on the Mechanical Properties of Steel*. [Gives the results of tests made on steels containing small amounts of

other metals as copper, tin, silicon, phosphorus, sulphur, etc.]—Iron & Steel Inst. Adv. Copy; pp 91*; 50c.

(II) NON-METALS

(A) FUELS

Coal Fields and Mining

Crankshaw, H. M.—*Methods of Mining in the Anthracite Field*. [The formation here is more thin and more nearly flat than in the other fields and mining machines and slushing here find a better application].—Coal Age Sept. 30 1916; p 530; pp 4*; 20c.

Evans, David.—*Nationalization of Coal Mines*. [A discussion of the subject from the point of view that this will be necessary because of the conflicts now starting between labor and capital in Great Britain].—I. & C. Tr. Rev. Sept. 8 1916; p 271; pp 2½; 35c.

Fay, Albert H.—*Monthly Statement of Coal Mine Fatalities in the United States*. [Contains a list of permissible explosives, lamps and motors tested prior to Aug. 31 1916].—Bur. of Mines Statement July 1916; pp 28.

Fear, Thomas G.—*Getting Clean Coal*. [A paper read before the Alabama Coal Operators' Assn. It states that the human factor, methods of mining and dockage have considerable to do with the question].—Coal Age Sept. 30 1916; p 541; pp 1½; 20c.

Graham, J. Ivon.—*The Occlusion of Gases by Coal*. [A paper read before the Institution of Mining Engineers, dealing with the permeability of coal, with respect to gases, etc.].—Coll'y Guard, Sept. 15 1916; p 513; pp 1. I. & C. Tr. Rev. Sept. 15; p 308; pp 1; 35c.

Hines, Richard P.—*Natural Gas Operating Coal Mines*. [Speaks of a central gas power station of the Consolidated Coal Co., W. Va., and the distribution of the electricity from this station to the mines].—C. Tr. Bull. Oct. 2 1916; p 34; pp 1¾; 25c.

Hopwood, William.—*Mining and Dealing with Mine Water in the Buckley Coalfield, England*. [A paper read before the National Assn. of Colliery Mgrs. Details are given of the methods used in this mine].—I. & C. Tr. Rev. Sept. 15 1916; p 314; pp 3*; 35c.

Smith, Watson.—*Early and Modern Coal Mining Methods in Japan*. [From the Jnl. of the Royal Soc. of Arts, being a brief general description of the mines in the country].—C. Tr. Bull. Oct. 2 1916; p 43; pp 1¾; 25c.

Sterling, J. T.—*Mine Rescue Work Developed in Alberta*. [Abst. from a paper read before the Canadian Mg. Inst., being a general description of the advances made along that line in the province].—C. Tr. Bull. Oct. 2 1916; p 34; pp 1¼; 25c.

Warden-Stevens, F. J.—*Coal and Bunkering Ports of Canada*. [Speaks of the extent of operations of bunkers in the Dominion].—I. & C. Tr. Rev. Sept. 8 1916; p 449; pp 3*; 35c.

—*British Association for the Advancement of Science*. [A report of the Fuel Economy Committee dealing with the use, consumption and conservation of coal in different industries].—Coll'y Guard, Sept. 15 1916; p 499; pp 4*. I. & C. Tr. Rev. Sept. 15; p 299; pp 5*; 35c.

—*Carriden Coal Co.'s New Pits, England*. [Describes the formation and methods and equipment used in sinking its No. 1 and 2 shafts].—Coll'y Guard, Sept. 15 1916; p 497; pp 1½*; 35c.

Coke

—*A Modern Plant for Making Coke*. [Describes how coke and by-products are made on a commercial scale].—I. Tr. Rev. Sept. 14 1916; p 515; pp 1½*; 25c.

—*Boilers Heated by Coke-Oven Gas*. [On equipment and installations for following this practice. Drawings are given with description].—I. & C. T. Rev. Sept. 8 1916; p 280; pp 1½*; 35c.

Petroleum

Smith, Warren D.—*Oil Fields of Tayabas Peninsula, Philippine Islands*. [An account of the oil possibilities in the Philippines].—Oil Age Sept. 1916; p 9; pp 2; 35c.

—*Oil Prospects in Ecuador*. [A general review of the industry in that country].—Calif. Derrick Sept. 1916; p 3; pp 1¼; 30c.

Natural Gas

Hines, Richard P.—*Natural Gas Operating Coal Mines*. [Speaks of a central gas-power station of the Consolidated Coal Co., W. Va., and the distribution of the electricity from this station to the mines].—C. Tr. Bull. Oct. 2 1916; p 34; pp 1¾; 25c.

Zanetti, J. E.; Leslie, E. H.—*The Therman Decomposition of the Ethane-Propane Fraction from Natural Gas Condensate*.—Jnl. Ind. & Engg. Chem. Sept. 1916; p 777; pp 2*; 60c.

III. TECHNOLOGY

MINES AND MINING

Surveying and Drafting

McCullough, Ernest.—*Practical Surveying for Surveyors' Assistants, Vocational and High Schools*. [In a practical way what a surveyor is supposed to do, methods and surveying laws are explained.].—Van Nostrand Co.; book; pp 400*; \$2.

Reeves, Edward A.—*Surveying, Past and Present*. [A review of surveying instruments from ancient to present times].—Jnl. of Royal Soc. of Arts. Sept. 15 1916; p 733; pp 13*; 35c.

Shafts and Shaft Sinking

Hall, Albert E.—*Shaft Timbering Examples*. [Drawings and description of various methods of shaft timbering are given].—E. & M. J. Sept. 30 1916; p 589; pp 1¾*; 25c.

—*Carriden Coal Co.'s New Pits, England*. [Describes the formation and methods and equipment used in sinking its No. 1 and 2 shafts].—Coll'y Guard, Sept. 15 1916; p 497; pp 1½*; 35c.

Ventilation

Chambers, G.—*The Atmospheric Problem in the Deepest Mine*. [Excerpts from the superintendent's report of the Morro Velho mine of the St. John del Rey Mining Co., Brazil, dealing with the ventilation of the mine].—Mg. World Sept. 30 1916; p 575; pp 2; 10c.

Sampson, R. J.—*An Economical System of Mining*. [The system allows of complete extraction of the ground at a low cost and consists mostly of pillar drawing. A tenacious sandstone roof permits the running of wide entries].—Coal Age Sept. 23 1916; p 491; pp 2¼*; 20c.

Lighting

Bullard, E. W.—*Introduction of the Acetylene mine Lamp on the Pacific Coast*.

[An account with some details on the introduction of this lamp].—Acetylene Jnl. Oct. 1916; p 185; pp 1½; 20c.

Fay, Albert H.—*Monthly Statement of Coal Mine Fatalities in the United States*. [Contains a list of permissible explosives, lamps and motors tested prior to Aug. 31 1916].—Bur. of Mines Statement July 1916; pp 28.

—*Illumination*. [A general review of proper illumination with respect to safety on surfaces].—Anode Sept. 1916; p 1; pp 2; 20c.

Dredging

Jennings, Hennen.—*Dredging in Montana*. [From a U. S. G. S. bulletin giving costs of operation and construction of dredges used].—M. & S. P. Sept. 23 1916; p 465; pp 2½*; 20c.

Purinton, C. W.; Smith, R. E.—*Winter Shuicing at the Lenskoi Gold Mines, Siberia*. [Describes the methods and plant used for handling the frozen gravel by thawing and treating at once. Mining, construction and other operating costs are given].—Mg. Mag. Sept. 1916; p 143; pp 9*; 50c.

Accidents

Fay, Albert H.—*Monthly Statement of Coal Mine Fatalities in the United States*. [Contains a list of permissible explosives, lamps and motors tested prior to Aug. 31 1916].—Bur. of Mines Statement July 1916; pp 28.

Fay, Albert H.—*Production of Explosives in the United States*. [Also contains notes on coal mine accidents due to explosives and a list of permissible explosives, lamps and motors tested before May 1 1916].—U. S. Bureau of Mines Tech. Paper 159; pp 24; 15c.

Rescue and First-Aid

Boardman, J. L.—*First Aid for Broken Bones*. [Reviews the nature of fractures and first aid methods for treating the same].—Anode Sept. 1916; p 8; pp 2*; 20c.

Sterling, J. T.—*Mine Rescue Work Developed in Alberta*. [Abst. from a paper read before the Canadian Mg. Inst., being a general description of the advances made along that line in the province].—C. Tr. Bull. Oct. 2 1916; p 34; pp 1¼; 25c.

Safety

—*Illumination*. [A general review of proper illumination with respect to safety on surface].—Anode Sept. 1916; p 1; pp 2; 20c.

Labor and Management

Bain, H. Foster.—*Labor Problems in African Mines*. [A discussion of labor, its comparative costs, with mine production, and a general description with respect to their ways and character].—Mg. Mag. Sept. 1916; p 135; pp 8*; 50c.

Evans, David.—*Nationalization of Coal Mines*. [A discussion of the subject from the point of view that this will be necessary because of the conflicts now starting between labor and capital in Great Britain].—I. & C. Tr. Rev. Sept. 8 1916; p 271; pp 2½; 35c.

Ridge, Fred H., Jr.—*Importance of the Human Factor*. [Deals with efficiency from the point of keeping the employee in a good attitude and state of mind towards his employer].—E. & M. J. Sept. 23 1916; p 543; pp 2; 25c.

Production

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*The Manganese Ores of the Lafayette District, Minas Gerais, Brazil*. [Separate description on different dis-

tricts and mines, also the nature of the ore and geology].—Bull. A. I. M. E. Oct. 1916; p 1745; pp 18*; 35c.

—British Association for the Advancement of Science. [A report of the Fuel Economy Committee, dealing with the use, consumption and conservation of coal in different industries].—Coll' Guard. Sept. 15 1916; p 499; pp 4*. 1. & C. Tr. Rev. Sept. 15; p 299; pp 5*; 35c.

Mining Costs

Bain, H. Foster.—*Labor Problems in African Mines*. [A discussion of labor, its comparative costs, with mine production, and a general description, with respect to their ways and character].—Mg. Mag. Sept. 1916; p 135; pp 8*; 50c.

Purinton, C. W.; Smith, R. E.—*Winter Sluicing at the Lenskoi Gold Mines, Siberia*. [Describes the methods and plant used for handling the frozen gravel by thawing and treating at once. Mining construction and other operating costs are given].—Mg. Mag. Sept. 1916; p 143; pp 9*; 50c.

Scott, Herbert K.—*Manganese Ores of the Bukovina, Austria*. [A concise but complete description of the country, the ores, geology, methods of handling and preparing and costs of the same].—Iron & Steel Inst. Adv. Copy 5; pp 20*; 50c.

Mining Miscellany

Miller, Benjamin L.; Singewald, Joseph T., Jr.—*Conditions Governing Mining in South America*. [From Teniente Topics in which a general review of operations in South American countries is given and conditions controlling the same are brought out].—Mg. World Sept. 23 1916; p 541; pp 1½; 10c.

—*Conversion Table for the Valuation of Ores, Minerals and Metals*. [A table for converting various English money values into the corresponding U. S. currency value].—Mg. Mag. Sept. 1916; p 152; pp 4; 50c.

MILL AND MILLING

Sampling

Woodbridge, T. R.—*Ore Sampling Conditions in the West*. [Excerpts from advance proofs of Tech. Paper 86 of the U. S. Bureau of Mines. Six methods of sampling are described which are in common use in the west and the particular classes of sampling for which each is fitted is given].—Mg. World Sept. 23 1916; p 537; pp 2; 10c.

Crushing, Grinding, Etc.

Burch, H. K.—*The Inspiration Mine Plant*. [Abst. from a paper read before the A. I. M. E. Describes the equipment and methods used for handling the ore from the mine, both underground and on surface].—E. & M. J. Sept. 23 1916; p 537; pp 5¾*; 25c.

Flotation

Clayton, C. Y.—*Experiments from the Flotation Laboratory*. [Considerable of the text has to do with the nature of different oils. Description of laboratory flotation machines and tests made on different ores are also given].—Mo. School of Mines Bull. Aug. 1916; pp 40*.

Elmore, A. Stanley.—*The Invention, Development and Introduction of the Flotation Process*. [A general historical account of the process carrying the method to a point where it was practically introduced].—M. & S. P. Sept. 23 1916; p 449; pp 6½; 20c.

Gahl, Rudolf.—*History of the Flotation*

Process at Inspiration, Arizona. [A paper read before the A. I. M. E., dealing in detail with the subject and equipment used].—Met. & Chem. Engg. Oct. 1 1916; p 393; pp 12½*; 35c.

Concentration: Sorting, Sizing, Washing

Scott, Herbert K.—*Manganese Ores of the Bukovina, Austria*. [A concise but complete description of the country, the ores, geology, methods of handling and preparing, and costs of the same].—Iron & Steel Inst. Adv. Copy 5; pp 20*; 50c.

Scott, W. A.—*Operations in the Tintic District, Utah*. [Describes the district and its operations in general and then gives separate descriptions of the operations and methods of some of the companies].—Mg. World Sept. 30 1916; p 583; pp 1¾; 10c.

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*Silver-Tin Mining in Bolivia*. [Old stope filling is being taken out, chloridized, leached and then concentrated for the tin residue].—E. & M. J. Sept. 23 1916; p 533; pp 3*; 25c.

Amalgamation

Allingham, John.—*Treating Amalgamation Tailings with Cyanide*.—E. & M. J. Sept. 30 1916; p 591; pp 1; 25c.

Purinton, C. W.; Smith, R. E.—*Winter Sluicing at the Lenskoi Gold Mines, Siberia*. [Describes the methods and plant used for handling the frozen gravel by thawing and treating at once. Mining, construction and other operating costs are given].—Mg. Mag. Sept. 1916; p 143; pp 9*; 50c.

Cyaniding

Allingham, John.—*Treating Amalgamation Tailings with Cyanide*.—E. & M. J. Sept. 30 1916; p 591; pp 1; 25c.

Clevenger, G. H.—*Electrolytic Precipitation from Cyanide Solutions*. [A paper read before the American Electrochemical Soc.].—E. & M. J. Sept. 30 1916; p 579; pp 3½*; 25c.

Edmonds, H. R.—*Some Notes on the Effect of Lead Salts and of Varying Degree of Alkalinity on the Solvent Power of Cyanide Solution for Gold*. [Gives the results of some tests made].—Monthly Jnl. Chamber of Mines West Aust. June 30 1916; p 108; pp 4½; 35c.

Mill and Smelter Costs

Crowley, John A.—*The Gronwall-Dixon Electric Furnace*. [A paper read before the American Foundrymen's Assn. Deals with the construction of the furnace, its operation and gives drawing and detailed costs of producing steel with the same].—I. Tr. Rev. Sept. 21 1916; p 571; pp 2½*; 25c.

Scott, Herbert K.—*Manganese Ores of the Bukovina, Austria*. [A concise but complete description of the country, the ores, geology, methods of handling and preparing and costs of the same].—Iron & Steel Inst. Adv. Copy 5; pp 20*; 50c.

Mill Miscellany

—*Conversion Table for the Valuation of Ores, Minerals and Metals*. [A table for converting various English money values into the corresponding U. S. currency value].—Mg. Mag. Sept. 1916; p 152; pp 4; 50c.

CHEMISTRY AND ASSAYING

Chemistry

Van Name, R. G.; Hill, D. U.—*On the Rates of Solution of Metals in Ferric*

Salts and in Chromic Acid. [A discussion and description of experimental work. The nature of the different experiments and results obtained are given].—American Jnl. of Sci. Oct. 1916; p 301; pp 3½*; 60c.

Chlorination

Singewald, Joseph T., Jr.; Miller, Benjamin L.—*Silver-Tin Mining in Bolivia*. [Old stope filling is being taken out, chloridized, leached and then concentrated for the tin residue].—E. & M. J. Sept. 23 1916; p 533; pp 3*; 25c.

METALLURGY

Electrometallurgy

Clevenger, G. H.—*Electrolytic Precipitation from Cyanide Solutions*. [A paper read before the American Electrochemical Society].—E. & M. J. Sept. 30 1916; p 579; pp 3½*; 25c.

Rawdon, Henry S.—*Notes on the Occurrence and Significance of Twinned Crystals in Electrolytic Copper*. [A paper read before the American Inst. of Metals].—Met. & Chem. Engg. Oct. 1 1916; p 406; pp 3*; 35c.

Sims, Clarence E.; Ralston, Oliver C.—*The Electrolytic Recovery of Lead from Brine Leaches*. [A paper read before the American Electrochemical Soc.].—Met. & Chem. Engg. Oct. 1 1916; p 410; pp 4*; 35c.

Thermic Metallurgy

Stead, J. E.—*Notes on Nickel Steel Scale and on the Reduction of Solid Nickel and Copper Oxides by Solid Iron*. [Gives the method of procedure and results obtained in experimental work].—Iron & Steel Inst. Adv. Copy 7A; pp 9*; 50c.

Hydro-Metallurgy

Sims, Clarence E.; Ralston, Oliver C.—*The Electrolytic Recovery of Lead from Brine Leaches*. [A paper read before the American Electrochemical Soc.].—Met. & Chem. Engg. Oct. 1 1916; p 410; pp 4*; 35c.

Metallurgy General

—British Association for the Advancement of Science. [A report of the Fuel Economy Committee dealing with the use, consumption and conservation of coal in different industries].—Coll' Guard. Sept. 15 1916; p 499; pp 4*. 1. C. Tr. Rev. Sept. 15; p 299; pp 5*; 35c.

POWER AND MACHINERY

Electricity

Campbell, Edward D.—*The Influence of Heat Treatment on the Thermo-Electric Properties and Specific Resistance of Carbon Steels*. [The results and nature of the tests are described and 8 curves are reproduced, showing the results of these and other tests].—Iron & Steel Inst. Adv. Copy 2; pp 18*; 50c.

Fay, Albert H.—*Monthly Statement of Coal Mine Fatalities in the United States*. [Contains a list of permissible explosives, lamps and motors tested prior to Aug. 31 1916].—Bur. of Mines Statement July 1916; pp 28.

Hines, Richard P.—*Natural Gas Operating Coal Mines*. [Speaks of a central gas-power station of the Consolidated Coal Co., W. Va., and the distribution of the electricity from this station to the mines].—C. Tr. Bull. Oct. 2 1916; p 34; pp 1¾; 25c.

Thornton, W. M.—*Influence of Pressure on the Electrical Ignition of Methane*. [A paper read before the British Assn., Sec. G, dealing with experimental work. Curves are shown].—Colly Guard. Sept. 15 1916; p 503; pp 2*; 35c.

Walker, Sydney F.—*Electric Signaling with Bare Wires*. [A general talk on proper practice resulting from investigations in England].—I. & C. Tr. Rev. Sept. 8 1916; p 279; pp 1; 35c.

—*Russian Mines, Growth of Electrical Equipment in*. [Gives details as to the number, size, etc., of electrical plants at mines in Russia].—C. Tr. Bull. Oct. 2. 1916; p 47; pp 3½; 25c.

Combustion Engines

Garrard, A.—*Gas, Oil and Petrol Engines*. [Deals with the history of combustion engines, their construction and use and the operation of equipment used in connection with them].—Whittaker & Co., London; book; pp 221*; \$1.50.

Hines, Richard P.—*Natural Gas Operating Coal Mines*. [Speaks of a central gas-power station of the Consolidated Coal Co., W. Va., and the distribution of the electricity from this station to the mines].—C. Tr. Bull. Oct. 2 1916; p 34; pp 1¼; 25c.

Watkinson, W. H.—*Starting Diesel Engines with Low Compression*. [A paper read before Sec. G of the British Assn. Treats on experiments made to show the possibility of running Diesel engines with low-compression].—Engg. Sept. 22 1916; p 290; pp 1*; 35c.

Steam and Steam Engines

Bowron, Charles E.—*Factors Governing the Efficiency of Steam Plants*. [A general discussion of the subject read before the Alabama Coal Operators' Assn.].—Coal Age Sept. 30 1916; p 539; pp 2½; 20c.

Hirshfield, C. F.—*Steam Power*. [An elementary treatise on the subject, omitting the deeper mathematics of the subject and the theory of thermodynamics].—Wiley & Sons; book; pp 420*; \$2.

—*Boilers Heated by Coke-Oven Gas*. [On equipment and installations for following this practice. Drawings are given with description].—I. & C. Tr. Rev. Sept. 8 1916; p 280; pp 1½*; 35c.

—*British Association for the Advancement of Science*. [A report of the Fuel Economy Committee, dealing with the use, consumption and conservation of coal in different industries].—Colly Guard. Sept. 15 1916; p 499; pp 1*. I. & C. Tr. Rev. Sept. 15; p 299; pp 5*; 35c.

Miscellaneous Power and Machinery

Abady, Jacques.—*Soot Blowers*. [A paper read before the Nottingham Guild of the Mechanical and Electrical Engineers, giving the advantages and operating methods of mechanical soot blowers].—Pract. Eng. Oct. 1 1916; p 827; pp 1½*; 20c.

Kent, Robert Thurston.—*Power Transmission by Leather Belting*. [Tables, formulas, theory and practical information regarding the practical use of belting in power transmission are given].—Wiley & Sons; book; pp 114*; \$1.25.

Kimball, G. H.—*A Serviceable Oiling System*. [On the development of a unit engine oiling system for reusing oil].—Pract. Eng. Oct. 1 1916; p 831; pp 1½*; 20c.

Mann, F. W.—*Lubrication and Lubricating Oils*. [From an address before the American Petroleum Soc., dealing on the theory of lubrication and the properties

and requirements of good lubricants].—Pract. Eng. Oct. 1 1916; p 833; pp 1½; 20c.

IV. MISCELLANEOUS

Testing

Campbell, Edward D.—*The Influence of Heat Treatment on the Thermo-Electric Properties and Specific Resistance of Carbon Steels*. [The results and nature of the tests are described and 8 curves are reproduced showing the results of these and other tests].—Iron & Steel Inst. Adv. Copy 2; pp 18*; 50c.

Clayton, C. Y.—*Experiments from the Flotation Laboratory*. [Considerable of the text has to do with the nature of different oils. Description of laboratory flotation machines and tests made on different ores are also given].—Mo. School of Mines Bull. Aug. 1916; pp 40*.

Gahl, Rudolf.—*History of the Flotation Process at Inspiration, Arizona*. [A paper read before the A. I. M. E. dealing in detail with the subject and equipment used].—Met. & Chem. Engg. Oct. 1 1916; p 393; pp 12½*; 35c.

Stead, J. E.—*Influence of Some Elements on the Mechanical Properties of Steel*. [Gives the results of tests made on steels containing small amounts of other metals as copper, tin, silicon, phosphorus, sulphur, etc.].—Iron & Steel Inst. Adv. Copy; pp 91*; 50c.

Stead, J. E.—*Notes on the Effect of Blast-Furnace Gases on Wrought Iron*. [Tests of various kinds were made to determine this effect].—Iron & Steel Inst. Adv. Copy 7C; pp 7*; 50c.

Thornton, W. M.—*Influence of Pressure on the Electrical Ignition of Methane*. [A paper read before the British Assn., Sec. G, dealing with experimental work. Curves are shown].—Colly Guard. Sept. 15 1916; p 503; pp 2*; 35c.

Van Name, R. G.; Hill, D. U.—*On the Rates of Solution of Metals in Ferric Salts and in Chromic Acid*. [A discussion and description of experimental work. The nature of the different experiments and results obtained are given].—American Jnl. of Sci. Oct. 1916; p 301; pp 31½*; 60c.

Watkinson, W. H.—*Starting Diesel Engines with Low Compression*. [A paper read before Sec. G of the British Assn. Treats on experiments made to show the possibility of running Diesel engines with low-compression].—Engg. Sept. 22 1916; p 290; pp 1*; 35c.

Metallography

Brearley, A. W.—*Some Properties of Ingots*. [A metallographic review of the peculiarities of ingots made under varying conditions. Reproductions of the structure of the steel are shown].—Iron & Steel Inst. Adv. Copy 1; pp 34*; 50c.

Hayward, Carle R.—*The Effect of Sulphur on Low-Carbon Steel*. [A review of metallographic tests, giving both the structure and change in physical properties due to the presence of sulphur].—Bull. A. I. M. E. Oct. 1916; p 1841; pp 10*; 35c.

Howe, Henry M.—*Recrystallization After Plastic Deformation*. [Deals with recrystallization after the cold-working of brass].—Bull. A. I. M. E. Oct. 1916; p 1851; pp 10*; 35c.

Rawdon, Henry S.—*Notes on the Occurrence and Significance of Twinned Crystals in Electrolytic Copper*. [A paper

read before the American Inst. of Metals].—Met. & Chem. Engg. Oct. 1 1916; p 406; pp 3*; 35c.

History

Gahl, Rudolf.—*History of the Flotation Process at Inspiration, Arizona*. [A paper read before the A. I. M. E. dealing in detail with the subject and equipment used].—Met. & Chem. Engg. Oct. 1 1916; p 393; pp 12½*; 35c.

Garrard, A.—*Gas, Oil and Petrol Engines*. [Deals with the history of combustion engines, their construction and use and the operation of equipment used in connection with them].—Whittaker & Co., London; book; pp 221*; \$1.50.

Reeves, Edward A.—*Surveying Past and Present*. [A review of surveying instruments from ancient to present times].—Jnl. of Royal Soc. of Arts Sept. 15 1916; p 733; pp 13*; 35c.

Scott, Herbert K.—*Manganese Ores of the Bukovina, Austria*. [A concise but complete description of the country, the ores, geology, methods of handling and preparing and costs of the same].—Iron & Steel Inst. Adv. Copy 5; pp 29*; 50c.

Smith, Watson.—*Early and Modern Coal Mining Methods in Japan*. [From the Jnl. of the Royal Soc. of Arts, being a brief general description of the mines in the country].—C. Tr. Bull. Oct. 2 1916; p 43; pp 1¼; 25c.

Societies

—*American Chemical Society, New York Meeting, Sept. 26 1916*.—Met. & Chem. Engg. Oct. 1 1916; p 379; pp 2½; 35c.

—*American Electrochemical Society, New York Meeting, Sept. 27 1916*.—Met. & Chem. Engg. Oct. 1 1916; p 381; pp 3½; 35c.

—*American Institute Holds Successful Meeting in the Southwest*. [An account of the proceedings of the meeting held during Sept.].—Mg. World Sept. 30 1916; p 577; pp 2; 10c.

—*American Institute of Chemical Engineers*. [Proceedings of the 8th semi-annual meeting, Cleveland, June, 1916].—American Inst. of Chem. Eng. Bull. 13; pp 48; 35c.

—*American Mining Congress, Chicago Meeting*.—Mg. World Sept. 30 1916; p 581; pp 1¼; 10c.

—*British Association*.—I. & C. Tr. Rev. Sept. 15 1916; p 304; pp 1; 35c.

General Miscellany

Rickard, T. A.—*J. Parke Channing and Copper Mining*. [A bibliography of Channing's life with respect to the mining industry, principally iron and copper in this country].—M. & S. P. Sept. 30 1916; p 487; pp 12*; 20c.

Turneaure, F. E.; Johnson; Bryan.—*Theory and Practice of Modern Framed Structures*. [Deals mostly with proportioning the members after the stresses are known and will be of most value to the student].—John Wiley & Sons; book; pp 486*; \$1.

Wood, George McLane.—*Reports on Mining Districts—General Suggestions*. [Abst. from a paper of a similar title written for use in the U. S. G. S. being a guide for the correct way to write reports].—M. & S. P. Sept. 30 1916; p 499; pp 4; 20c.

—*Making Mine Engineering Calculations*. [A general talk on the use of mechanical appliances of use in making computations].—Mg. World Sept. 30 1916; p 579; pp 1½*; 10c.

Ore and Metal Markets; Prices-Current

New York, Oct. 17, 1916.

Silver.—Quotations for silver per fine ounce at New York and per standard ounce at London during the week ended Oct. 18 were as follows:

	New York, cents.	London, pence.
Oct. 12.....	67 3/8	32 15/16
13.....	67 3/8	32 7/16
14.....	68	32 1/2
16.....	68 1/4	32 9/16
17.....	67 3/4	30 1/2
18.....	67 3/4	30 5/16

*Holiday.

MONTHLY AVERAGE PRICES OF SILVER.

Month.	New York			London	
	High.	Low.	Avg.	Standard Oz.	Avg.
January	57%	55%	56.775	26.875	22.744

September	69 1/4	67%	68.515	49.385	23.923
October	51.713	24.640
November	55.038	26.232
December

Year 49.690 23.470

Difference in domestic and foreign prices explained by the fact that the New York quotations are per fine ounce; the London per standard ounce 8.925 fine.

Copper.—Buying of copper since our last report has totaled about 10,000,000 lbs. Domestic consumers were in the market for some fairly large-sized blocks of the red metal for first quarter delivery, but with all the large foreign and domestic consumers protected the market lacks the inspiring features that were evident in recent weeks. Spot electrolytic sold at 29 1/4 cts., with November at 28 1/2 cts. and December at 28 1/4 cts., these prices being on sales by dealers. Producers took orders for January at 28 cts., with first quarter business done at 27 1/2 cts. and second quarter at 27 cts. Casting copper held at 27 1/2 cts. for spot, with the same price asked for November delivery. Prime lake copper on the spot and for November sold at 28 1/2 @ 28 3/4 cts.

As yet the bear movement by dealers to secure blocks of metal for the first half has not made its appearance. With buying by consumers over, the dealers usually try to uncover a weak spot in the situation and thus stock up metal at lower prices, but all of the producers are well sold up and the likelihood of a bear movement being successful is not considered bright.

Exports of copper since the first of the month total 9752 tons. The copper export situation is being aided by lower ocean freight rates and also a greater supply of shipping facilities. Two large shipments of copper have been destroyed, one on the *Stephano*, sunk by the U-53, and the other on the steamer *Milazzo*, destroyed by fire in the Azores.

The London market has pursued a steady upward course, electrolytic last week going up £1 to £143, while standard advanced £2 to £123 and futures £1 10s to £118 10s. Stocks of copper in Europe on Oct. 15 totaled 5620 tons, as against 5796 tons on Oct. 1, a decrease of 176 tons. The supply afloat was 6050, as compared with 5575 tons, an increase of 475 tons, so that the total visible supply on Oct. 15 was 11,670 tons, as contrasted with 11,371 tons on Oct. 1, showing an increase of 299 tons.

Quotations for copper per pound at New York for the week ended Oct. 18 were as follows:

	Lake.	Electrolytic.	Casting.
Oct. 12.....	28 1/2 @ 29	28 1/2 @ 29	27 @ 27 1/2
13.....	28 1/2 @ 29	28 1/2 @ 29	27 @ 27 1/2

14.....	28 1/2 @ 29	28 1/2 @ 29	27 @ 27 1/2
16.....	28 1/2 @ 29	28 1/2 @ 29	27 1/4 @ 27 1/2
17.....	28 1/2 @ 29	28 1/2 @ 29	27 1/4 @ 27 1/2
18.....	28 1/2 @ 29	28 1/2 @ 29	27 1/4 @ 27 1/2

Quotations for copper per ton at London for the week ended Oct. 18 were as follows:

	Standard		Electrolytic.
	Spot.	Futures.	
Oct. 12.....	£123 0 0	£118 10 0	£142 10 0
13.....	123 0 0	118 10 0	143 0 0

Tin.—The submarine scare has passed and tin prices, after showing some very sharp advances, have receded to levels more compatible with the technical position of the metal. The steamers *City of Naples* and the *Lancastrian* have arrived and the trade once more breathes easily. The upward spurt in prices served to bring many consumers into the market and sales of about 850 tons for all deliveries were made. Tin plate manufacturers were the principal buyers, covering requirements involved in new plate contracts.

Spot Straits tin sold at 43 cts. and spot Banka up to 42 1/2 cts., with business for the first 3 months' arrival done at 42 cts. Spot Straits is now holding quiet and rather easy at 41 1/4 cts.

with spot Banka at 40 $\frac{3}{4}$ cts. For November and December arrival sellers ask 41 $\frac{1}{2}$ cts., with January, February and March at 40 $\frac{3}{4}$ cts. and May and June at 40 $\frac{3}{4}$ cts.

Independent tin plate makers set their price for 1917 at \$6 per base box, but the American Sheet & Tin Plate Co. fixed \$5.75 as its price and pending a readjustment of the difficulty herein involved buying of tin is likely to be quiet.

London and Singapore made capital of the nervousness here, Singapore going up to £187 10s, but subsequently declining to £185. Straits tin at London advanced to £181 and now holds at £179 10s. Limits from the east were strong at 40 $\frac{3}{4}$ @41 cts. for shipments up to March and with a large portion of the offerings accepted the sharp advances abroad were not surprising. Statistically the position of tin is very good.

Arrivals total 1180 tons, while the stock afloat aggregates only 2350 tons, of which 1750 tons is on known steamers for October arrival. The small stock afloat favors a strong bull market.

Quotations for tin per pound at New York and per ton at London and Singapore for the week ended Oct. 18 were as follows:

Oct. 12.....	New York		London, Straits, spot.	Singapore, shipments.
	Spot.	Oct.

Lead.—Business has been small since our last report, but at this writing signs of an improvement in the demand are beginning to appear. Last week a slight easiness in the spot situation was noted, but this week the concessions are no longer obtainable. Producers' views are very firm, owing to the good position of their order books, and the drift toward lower levels in the outside market failed to disturb them. Canadians are expected to come into the market shortly for a large block of lead, while Russia is sounding the market. Spot moved off to 7 cts. New York and 6.80 cts. St. Louis, but has since advanced \$1 a ton.

The inaction of the American Smelting & Refining Co. with respect to changing its official price has mystified the trade, but an advance is regarded as certain before the end of the month. Domestic consumers are apparently well supplied by contracts and brokers who had odd lots of spot metal to offer reported difficulty in interesting users.

As a whole the lead situation is very strong and the continuation of high prices over the rest of the year is thought certain by producers. The London market has failed to show any animation, holding at £30 10s for spot and £29 10s for futures.

Quotations for lead per pound at New York and per ton at London for the week ended Oct. 18 were as follows:

Zinc Ore.—In the Missouri-Kansas-Oklahoma district last week zinc-ore prices were considerably stronger, ranging from \$62.50 to \$70. The average price paid was \$66.25. Production for the week amounted to 12,957,120 lbs. of a value of \$417,762. The year's production to date amounts to 519,127,290 lbs. of a value of \$22,059,288.

Calamine.—The market was firm, prices averaging around \$39.

Spelter.—Buyers withdrew from the spelter market as suddenly as they entered and producers who had figured that the upward movement in prices would compel consumers to cover requirements found that users were well protected and in a position to ignore the higher levels. Prices receded and business has been very dull. The speculative buyers withdrew following the submarine scare and have been absent since. What induced them to buy still remains a mystery, although there have been reports that some heavy foreign buying was about to materialize.

Prime western spelter moved off to 9 $\frac{3}{4}$ cts. New York and 9.55 cts. St. Louis for spot, while brass special eased off to 11 cts. St. Louis for spot. Prime western for November receded to 9.55 cts. St. Louis, with December down to 9.50 cts. and first quarter to 9 $\frac{3}{4}$ cts. Consumers have shown no interest in the metal.

As pointed out in this report 3 weeks ago, the situation is regarded by consumers as not warranting any fear of a drastic upward turn in prices and therefore there is no need

to cover needs well into the future as they did copper. The London market has also declined, spot dropping to £54 10s and futures to £51.

Quotations for spelter per pound at New York and per ton at London for the week ended Oct. 18 were as follows:

	New York.		London—

MISCELLANEOUS METALS.

Quicksilver.—There has been no change in the situation in the interim. Demand continues quite steady with the supply short and the price holds firmly at \$80 per flask for spot virgin metal. Foreign buyers are in the market, while domestic consumers appear to be seeking forward protection. Although there are no signs of an early change in the price, an advance would not surprise the trade in view of the scarcity.

Antimony.—On a fair amount of buying by Canadian consumers the price of antimony has advanced to 13 cts. for spot. Sellers reported that Italy was also in the market and took a fair amount for early shipment. Domestic consumers, however, are not greatly interested. As many of the domestic users are still taking antimony which they purchased last spring, at prices ranging from 45 cts. down to 30 cts., they are now inclined to wait until they actually need metal before again entering the market. The largest Chinese importer has been out of the market on spot goods, while other importers declare that supplies here are small. Most of the recent business has been for spot, but a fair amount of selling was done in November and December delivery.

Tungsten.—Business has been extremely quiet and sellers here state that it would be difficult to secure \$15 a unit from domestic consumers. Telegraphic advices from Colorado and California indicate that ore sellers in the west are asking \$20 a unit, but with eastern sellers unable to secure even \$15 the western price is out of the question. Leading consumers are importing large quantities from South America and are therefore independent of the domestic ore.

Platinum.—There has been no essential change in the situation in this metal. Refiners state that there is a fair demand, with the market steady at \$90 an ounce for soft and \$96 for hard metal.

Nickel.—Business is small in nickel with the market unchanged at 45 cts. for shot and ingots and 50 cts. for electrolytic metal. Sellers report that a few domestic orders have been obtained, but that foreign business is restricted.

Pig Iron.—Price advances in pig iron continue frequent and the upward movement is assuming a pace that is similar to that noted in steel about a year ago. Bessemer iron has sold up to \$24 valley and basic at \$20.50 valley.

Foundry grades are also securing a share of the activity, all prices being up from 50 cts. to \$1 a ton, while the cleaning of furnace banks has resulted in premiums on spot shipments.

Ferromanganese.—As yet there has been no change in ferromanganese prices, but an advance is looked for, especially with pig iron mounting to very high levels. Domestic producers are offering freely at \$166 delivered, while English alloy is obtainable at \$164 seaboard, although one sale at \$162 seaboard is noted.

Continuous Counter Current Agitation and Decantation

C. F. SPAULDING.

There is a very interesting article on "Counter Migration of Pulp and Solution in Cyanidation and Acid Leaching" by Bernard McDonald in the July 1st issue of the Mining and Engineering World.

Several years ago I built a small cyanide plant along those lines. There were three agitation tanks 20 by 20 ft., each tank being equipped with an inner annular ring, or tank, without top or bottom, and extending down 8 ft. from the top of the agitation tank. Each tank was equipped with four transfer pipes, substantially as described by Mr. McDonald.

The flow sheet of the mill is shown in Fig. 1. The ore as it came from the mine passed through a crusher to the ore bin, thence to a 5 by 22 ft. tube mill. The

discharge of the tube mill going to a 3-compartment jig classifier; the oversize returning to the tube mill and the slimes going to a thickening tank; the thickened pulp from the thickening tank going to No. 1 agitating tank, and the clear overflow being returned to the jig classifier.

In the agitating tanks the solids were settled out of the pulp in the inner ring; the clear solution (which usually stood 16 to 18 ins. above the surface of the pulp in the outer ring), was decanted off, and pumped by centrifugal pumps, to the zinc room at the top of the mill, some 40 ft. elevation above the agitating tanks. The pregnant solution passing through the zinc boxes, and the barren solution returning to the

agitating tanks, where it was forced into the bottom of the transfer pipes by gravity, assisting very materially with the agitation.

In 1910 at the Veta Colorado Mining & Smelting Co.'s cyanide plant at Parral, Mex., working with a base silver ore, I found by using barren cyanide solution for agitation instead of air agitation, that the time of agitation was cut from 72 hours to 48 hours, with an increased extraction of 15 to 20 grams silver.

The agitating tanks Nos. 2 and 3 were piped up similar to No. 1 tank, each tank having its own system of pumps and zinc boxes, etc.

The pulp as it passed out of the agitating tanks went to a V-bottomed settling box, the overflow solution being pumped to the head of the mill, and the settled tailings being discharged to waste. The make-up water for the mill was introduced at the head of the settling box.

In operating this mill I found that the area allowed for settling purposes was too small. To get around this difficulty I filled the inner settling space with clarifying filter leaves. The leaves were made with wooden frames filled with vertical wood slats and were covered with unbleached muslin. The muslin instead of being stitched through was held in place and kept from bulging by wood strips, spaced 12 ins. apart and held by carriage bolts. This construction worked out quite satisfactorily, and was considerably cheaper to install than regulation filter leaves with coco matting and canvas would have been.

The leaves were submerged in the thinned pulp and were connected to a manifold. At that time I was unable to secure a three-way valve that could be rigged up to work automatically, so I arranged the valves to be operated by hand, as it took 2 to 3 hours to form a cake, this was a minor item. The valves were arranged to cut off the vacuum pump and then allow the kick-off solution to enter the manifold and leaves under a low pressure; 10 lbs. pressure was used. This kicked-off the cake formed and allowed it to drop to the bottom of the agitating tank. The cakes being formed at a low vacuum and not being air dried or lifted from the pulp, were loose and flocculent and dissolved easily when they dropped to the bottom of the tank.

The introduction of the filter leaves solved the restricted settling area and also gave a clarified solution for precipitation, which was a good thing. I have been trying to settle solutions for precipitation purposes for a number of years, sometimes with good results and sometimes not so good. It seems that no matter how clear a decanted solution appears to be, it will foul zinc boxes much more rapidly than the same solution will after being passed through a clarifying filter. In decantation work one is usually crowding things to the limit, and unless watched very closely he can hardly avoid having a rush of slimes come over once in a while. I have stood on top of the Dorr thickening tanks at the Veta Colorado mill and have seen the slimes raise in the tanks until they began to run over the overflow lips; this condition would hold for a few minutes to half an hour, then things would go back to normal again. A certain proportion of this overflow solution was sent to the zinc house, where it was impoverished; this was done to keep the mill solutions from building up in silver; the muddy solution coming from the Dorr thickeners fouled the zinc boxes so badly that it forced the installation of clarifying filters.

McDonald's scheme is all right; the main points are to have sufficient settling area; or to install clar-

ifying filter leaves in the settling area; or, better yet, do both. All available data that I have been able to get, experimental and otherwise, show that 1 sq. ft. of settling surface will clarify 1 to 4 tons of solution per 24 hours. In the Dorr Cyanide Machinery Co.'s 1914 Bulletin, page 27, there is given some data on areas necessary to settle pulp:

Veta Colorado Co., Parral, Mex.

5 sq. ft. to settle 1 ton ore. Pulp 11 to 1.
5 sq. ft. to settle 11 tons solution.
1 sq. ft. to settle 2 1/5 tons solution.

At the Veta Colorado there were three 36 by 12 ft. Dorr thickening tanks; several times I had occasion to run all the pulp from the mill to one of these tanks; this meant settling some 3800 tons of pulp daily, or a duty of 3.3 tons of clear solution per square foot of tank area.

Noxia Scotia, Sonora, Mex.

5.4 sq. ft. to settle 1 ton of ore. Pulp 6 to 1.
5.4 sq. ft. to settle 6 tons of solution.
1 sq. ft. to settle 1.1 tons of solution.

Broken Hill Proprietary, Australia.

1356 sq. ft. to settle 5000 tons solution.
1 sq. ft. to settle 3.7 tons solution.

Another thing to figure on is to have some mechanical means of moving the settled solids towards the transfer pipes. I found that the circulation of the pulp in the outer ring did not assist in cutting down the cone formed in the center. When I estimated the size of the tanks I figured on a cone forming in the center of the tanks, with a slope of 45°. It formed all right, but the slope was nearer 90 than 45°. The sides would slide off and clog the transfer pipes. Some ores might not need this mechanical transference of the settled solids, but one experience without it is enough, and my next plant will have drag arms to move the settled solids, and will be designed along the lines of the flow sheet shown herewith.

In the mill I will change the agitating part from the outer ring to the inner ring, arranging the tanks similar to an elongated Dorr thickening tank, making the shaft driving the drag arms of 16 or 18 ins. extra heavy pipe, and utilizing this pipe as a transfer column. The settling action then is the same as it is in a standard Dorr thickening tank.

The solids, as they settle down, are dragged to the center of the tank. A certain proportion of the thickened pulp, equal to the tonnage coming into the tanks, is drawn off through the center draw-off plug, and passed to the next tank below. The balance of the thickened pulp is picked up by the agitating medium, either air or the solution coming up from the tank below, or both, and goes up through the transfer pipes to the top of the tank, where the solids begin to settle out, going through the same process again until they pass to the next tank, and finally out of the system.

The solution agitation may be assisted or not as desired by air agitation. Adding a little air along with the solution used for agitating accelerates the circulation of the pulp through the transfer pipes and also supplies the necessary oxygen. I have found that ordinarily the solutions will pick up enough oxygen from the surface contact with the air on top of the tanks and during the drop of a few inches from the top of the transfer pipes.

One tank at the Veta Colorado, using barren solution for agitation without any air, gave an increased extraction of 20 grams silver and cut the time for agitation from 72 hours to 40 hours. With air agitation,

as the solution becomes pregnant, the particles of gold and silver are surrounded with pregnant solution and the more gold and silver this solution carries the less its dissolving power. With solution agitation, as fast as the solution surrounding a particle of gold or silver becomes saturated, it is washed away or diluted with barren solution and stays in its most active form. It is a well-known fact that the old-fashioned agitation and decantation process, where the tanks were agitated, settled and decanted off, then more barren solution added and the tanks again agitated, settled and decanted, gave better extraction than the more modern processes of continuous agitation, either in series or separate charges followed by filter pressing in which the ore particles in the pulp stick pretty close to its own drop of solution.

Some 14 or 15 years ago I saw some interesting work done by the Holderman Filter Tank Co. of Salt Lake, with mechanical agitation. They used a horizontal shaft equipped with beater arms or paddles, the whole thing submerged in the pulp in a rectangular tank. This combination of mechanical heating with the air absorbed by the violently agitated mass gave an excellent and very rapid extraction. As I remember it seldom took over 30 minutes to put into solution all the soluble gold. They experimented with a number of ores from different parts of this country and Mexico.

An idea has occurred to me on which I am now working, and that is to enlarge the top of the transfer pipe in either a Pachuca or Parral tank, install therein a mechanical beater similar to that in a mechanically-driven flotation cell. Experiments on my tailings from a concentration and flotation plant, handling a complex lead-zinc-copper-silver ore, and to which are running too high in silver to suit, seem to indicate that mechanical beating in the top of the transfer pipes, combined with solution agitation, will cut the time of agitation 50 to 60% under what it would take with air agitation alone, and also give a higher recovery of the silver values.

An Original and Effective Mine Signal System.

The A. Hanna Coal Co., operating mines in northern Michigan, has equipped its shafts with a signaling system as effective as it is novel. Confronted with a signaling problem in connection with their cage operations, the mine officials co-operated with the Western Electric Co. in the design of a special system as indicated above.

The system and its operation are simple, being essentially as follows: At each of the various mine levels loud ringing extension bells are installed in pairs, each pair consisting of one 6-in. and one 8-in. weatherproof type loud-ringing gong. In connection with these bells, special switches are installed at each level. They consist of a telephone switch hook housed in a weatherproof cast iron casing. Attached to the switch hook and hanging from the casing is a long leather strap similar to the well-known street car strap. Pulling this strap makes contact and rings the 6-in. bells on every level, and one in the engineer's room. When a man has loaded a car and wants it hoisted, he pulls the leather straps a number of times—the number corresponding to a pre-arranged signal that corresponds to the operation desired. The bells ringing on each level in connection with the engineer's bell serves as a warning to the men on the various

levels. The 6-in. bells are on one circuit and the 8-in. bells on another—the latter being rung by the engineer when he is ready to hoist, or as a summons.

The wires of the signaling circuit are used for a telephone system, with a telephone set in the engineer's room, and a set on every level. The system is simply a magneto party line circuit, and is used as a means of communication in connection with the signaling system between the various levels and the levels and the engineer.

The company has placed great reliance in its new signal system and has taken great precaution to keep it in operation. A supplementary circuit has been wired so that if the ringing current in connection with the system should fail, warning bells will ring, summoning a repair man.

Recovering Quicksilver from Ores.

William H. Landers, of Almanden, Calif., has patented special apparatus for the recovery of quicksilver and assigned one-half interest to the Pacific Foundry Co., of San Francisco. The sectional view herewith illustrates the sequence of operations by which the quicksilver vapor is distilled off and the metal recovered without mingling with dust.

The ore in crushed condition, say from $\frac{3}{4}$ -in. mesh down, is roasted in the multiple hearth furnace. (A) The gases driven off, together with dust from the furnace, pass over into the dust settler. (B) In this settler the gases will remain hot enough to prevent the

LANDERS' METHOD OF RECOVERING QUICKSILVER.

precipitation or condensation of any quicksilver, and the settler has a form and is of such dimensions as to reduce the velocity of the gases and provide a quietness conducive to the settling out of the dust. The gases which now contain only a small amount of dust, if any, pass into through the condenser. (C) The quicksilver settles in the collecting boxes or trays of the condenser.

The condensation is due to the current air from the fan (D), passing through the baffle spaces of the condenser. The air quickly cools the pipes, and when it is liberated, it is in a heated condition and is discharged into the stack, increasing the draft and creating effective suction throughout the whole apparatus.

An important advance has been made within the past 2 years in the field of electrometallurgy in the development to a practical stage of an electrolytic process for the manufacture of iron.

Flotation at the Mt. Morgan Mine, Queensland

W. SHELLSHEAR.*

The Mount Morgan ore is a mixture of iron pyrites, copper pyrites, and gold in a quartzose gangue. There are two types of ore broken in the underground workings—smelting ore containing 40 to 50% silica, and ore too siliceous for economical smelting. This latter type of ore was treated by flotation, an approximate analysis being:

Copper	2.0%	Alumina	1.5%
Iron	10.0%	Calcium carbonate, al-	
Gold	5½ dwt.	kalis, etc.	3.5%
Silica	73.0%	Sulphur	10.0%

or, dividing the ore approximately into component minerals: Copper pyrites, 6%; iron pyrites, 16%; quartz calcite, etc., 78%. This analysis is only typical, and does not represent the average assay of the class of ore.

In order to carry on experiments on a large scale, a 6-box standard 24-in. Minerals Separation machine was installed. For 3 months occasional tests were made with the machine. It was then decided to convert the plant into a large-scale experimental unit treating 100 tons a day, in order that the value of concentrates produced would, to a large extent, defray experimental costs.

Following is a description of the plant, which, to the writer's knowledge, is the only dry-crushing plant used on a large scale for flotation treatment. The same ball mills, coarse crusher, and bins being used as were in use in the West Works before it closed down.

The ore from the shaft bins, approximately 6 ins. in size, was hauled in trucks and tipped into a bin of 400 tons capacity. From thence it was fed into a 24 by 16-in. Blake-Marsden crusher. The tonnage put through the machine was 10 to 15 tons per hour, and the horsepower was 20 to 26. The crushed product, varying in size from 1½ to 2 ins., was conveyed along one of the old West Works drier conveyors, and was elevated into bins above the ball mills by bucket elevators. Eight No. 5 ball mills were put into commission, of which six were constantly in use, traveling at 20 rpm. These were driven by pinion and spur-gearing off one main shaft, and each mill was capable of being thrown out of commission by means of clutch-gearing. Six-inch steel balls were added regularly with the feed so as to keep the normal weight of 1 ton of balls in each mill. Screens of 50-mesh were used (not I.M.M. standard screens), the average size of the crushed product being 10 to 15% + 60 mesh (I.M.M.).

Each mill took 15 hp. when crushing at its full capacity, which was approximately 0.9 to 1 ton per hour. The product from the ball mills passed into two fine-feed bins, each capable of holding 150 tons. To prevent escape of fine dust, each bin was lined with sheet iron. From these latter bins the ore was fed into the Minerals Separation plant by two Challenge feeders delivering into launders, with water pipes so arranged as to wet the ore with minimum escape of dust. The feeders were very accurate, and could control any required tonnage.

The arrangement for feeding the oil was similar to that at the Kyloe copper plant. The oil was supplied from a tank kept at a constant head by means of a ball valve which actuated a valve in the bottom of a

feed tank higher up. The speed of each agitator of the Minerals Separation machine was 205 revolutions, and the whole machine took from 55 to 60 hp., depending on the rate of feed.

The first one to five boxes were run for concentrates, and No. 6 box was returned to the feed by means of an elevator.

The concentrate was at first run into round vats, about 20 ft. in diameter and 10 ft. deep, with filter bottoms. These, however, were unsatisfactory, owing to the fact that the wet slime always kept to the outside of the vat and did not thoroughly drain. The difficulty was overcome by running the concentrate into a series of rectangular vats, 9 ft. 10 ins. by 10 ft. 9 ins., about 3 ft. deep, with cocoanut matting resting on a sand filter bed.

The concentrate was run through these in series, three or four always being in operation, and each vat

FLOW SHEET OF MOUNT MORGAN FLOTATION PLANT.

was filled with concentrate. No trouble, however, was experienced with this system. The drained water was perfectly clear, and the concentrate drained readily in 48 hours to 7 to 8% moisture. The residue was run into the creek.

Flotation Experiments.

As a general rule, acid is not used in the flotation of this type of ore, and this particular case was no exception. As typical of one of the many trial tests made on this plant before its conversion into a large-scale unit, the following results were obtained from a special quantitative test on a certain slope of the mine:

Data of Test.—Rate of feed, 15 tons per hour; dilution of pulp, 3.5 to 1; duration of run, 3 hours; ore (actual), 1 lb. per ton, eucalyptus being used; oil

*Excerpts from paper read before Australian Institute Mining Engineers.

was added—two-thirds to No. 1 mixer, one-third to No. 3 mixer.

Each flotation-box assayed separately gave the following results:

	Gold. dwt.	Copper. %	Iron. %	Silica. %
No. 1 box concentrate.....	55.52	16.28	34.49	10.10
No. 2 box concentrate.....	44.90	14.36	34.49	12.20
No. 3 box concentrate.....	40.00	12.84	32.72	17.53
No. 4 box concentrate.....	41.43	14.38	32.07	16.80
No. 5 box concentrate.....	25.36	8.10	27.08	32.81
No. 6 box concentrate.....	18.77	5.81	20.23	50.37

The theoretical recovery of gold in bulk on this test is about 76%, and, as seen from the sizing tests, it is much higher in the —120 grade than in any of the coarser grades. The relatively low recovery of gold as compared with that of copper led to a number of tests being carried out to try and find out the exact occurrence of the former.

Occurrence of Gold in Various Flotation Products.

Tests on Concentration of Ore by Tabling before Flotation.—Vanning tests, conducted in a dish in the laboratory on various stopes of the mine, indicated that a recovery of 40 to 50% of the gold could be obtained, but only about 30% of the copper, unless the crude ore vanned was very high in copper. On conducting flotation tests on the vanned residue more gold and copper were recovered. In the ore a high percentage of copper nearly always indicated a high gold content. The vanning concentrates, however, although much lower in copper than the flotation concentrates, were, as a general rule, higher in gold values.

Laboratory tests indicated strongly that, although the gold in bulk was associated with the copper, on fine crushing it certainly was not so associated. Tests were then conducted on a Wilfley table, sectional samples being taken every 9 ins. along the table to ascertain how the gold followed the various table products. Feed to table was crushed through 50-mesh screens on ball mills of main plant. Feed was sent direct to table without classification.

Table Details.—Speed, 260; stroke, $\frac{5}{8}$ -in.; fall, $\frac{1}{2}$ -in. per ft.; rate of feed, $1\frac{1}{4}$ tons per hour. A vanning test was conducted in a dish on a crude sample of sulphide ore assaying 25.14 dwt. of gold. After careful concentration a trace of very fine free gold could be seen on the edge of the dish. Concentrates produced were tested for tellurium; because, on rare occasions, telluride minerals have been found in this mine, but no trace was discovered.

Tests on Occurrence of Gold in Residue after Flotation.—A sample of residue from a large scale flotation test assayed 2.44 dwt. gold, 0.23% copper. The magnetite was removed carefully under water with a hand magnet, a fairly clean magnetite being obtained. This assayed 3.42 dwt. gold, proving that a certain proportion of the gold is with the gangue. The proportion of magnetite in the residue only represented a very small percentage of the total iron remaining there. The test indicated clearly that gold is not associated with copper.

Use of Sonstadt Solution.—A sample of flotation residue from a large-scale flotation test was taken assaying 4.40 dwt. gold, 0.55% copper. Sample was screened through an 80-mesh sieve. The —80 product was then screened through 120-mesh. The sand that remained on the 120-mesh sieve was used for the test. It assayed 5.13 dwt. gold and 0.74% copper.

Sonstadt solution was prepared by taking a saturated solution of potassium iodide in water and adding mercuric iodide till required specific gravity of

solution was obtained. In this case 150 grm. of the sand from the product sieved between —80 and +120-mesh was added to the Sonstadt solution and stirred well. The Sonstadt solution had to be kept warm to prevent it solidifying. The quartz product floated on top of the solution, and was skimmed off, filtered free of solution, and dried.

Assays of products obtained were—

	Gold. dwt.	Copper. %	Iron. %	Silica. %
Original product	5.13	0.74
Quartz product	3.91	0.05	1.45	95.50
Mineral product	9.79	1.85	34.95	18.40

As the mineral product contained 9.79 dwt. of gold, the copper and the iron in the quartz product certainly did not account for the total gold present. Therefore, the test proved that a certain percentage of the gold was associated with the quartz. In order to obtain still more information on this matter, the original sample of residue was screened through 120-mesh. The —120-mesh product was then screened through 180-mesh. The sand that remained on the 180-mesh screen was used for the second experiment. The test was conducted similarly to the first experiment, the quartz product being floated off the top of the Sonstadt solution. Assays of the quartz product were: Gold, 1.30 dwt.; copper, *nil*; iron, 0.79%. This test is of interest, as it clearly indicates that there was less gold associated with the quartz in the finer product. Hence, it seemed reasonable to assume that a certain amount of the gold associated with the quartz was liberated by finer crushing.

Tabling of Residue after Flotation.—Numerous tests were conducted on Wilfley tables in the experimental plant. The following are results of a typical test:

Table Details: Sectional Analysis.—Speed, 260; stroke, $\frac{5}{8}$ -in.; fall, $\frac{1}{2}$ -in. to ft.; feed, $\frac{3}{4}$ ton per hour. Feed crushed through 50-mesh screens and sent unclassified to table.

Average Extra Recovery of Gold by Tabling after Flotation.—Large-scale tabling tests proved that this varied considerably according to the stopes from which the ore was obtained, the recovery in some cases being practically *nil*, in others 10% on original feed. The following are the assay values on a typical table concentrate: 6.85 dwt. gold, 0.66% copper, 38.3% iron, 16.8% silica.

Examination of Flotation Concentrates.—Flotation concentrates were tested for tellurium, but no trace was found. A sample, being the —80 product of the first flotation-box concentrates and assaying 47.2 dwt., were vanned to see if any free gold was present. After long and careful vanning very fine free gold could be seen in the dish. This test proved conclusively that fine free gold floats, and that a certain proportion of it, at any rate, was free in the concentrates. It seemed reasonable to assume that the gold in the siliceous ore was free and in a very fine state of subdivision.

Flotation of the Iron.

As seen in figures of the flotation test, the recovery of iron was low. Results from many runs averaged 45 to 60%, the residue assaying 4 to 8% of iron. The percentage of iron varied considerably, according to the nature of the ore. The test indicated that gold was in a fine free state distributed through all the table products.

Recoveries of gold and copper during tests extending over a week at the experimental plant were

63.9 and 80.7% respectively. The results proved that some of the iron in the crude had no tendency to float even when crushed through 120-mesh. This was confirmed by numerous laboratory tests on ore crushed through 120-mesh. The average iron in flotation residue was 4 to 5%.

A sample of flotation residue from large-scale treatment was crushed through 120-mesh and was re-floated, giving the following results:

Product.	Gold. dwt.	Copper. %	Iron. %	Silica. %
Original residue	2.93	0.44	5.77
Concentrate	13.71	5.58	21.1	46.14
Residue after refloating.....	1.63	0.20	4.98
Recoveries on original residue	50.4	56.7	18.1

The light color and general appearance of the iron in the residue indicated that it was marcasite which was identified in this class of ore by Messrs. Newman and Campbell Brown.¹ The concentrates from tabling after flotation were found to oxidize very rapidly—usually in about 24 hours—while flotation concentrates did not oxidize, even after standing for days. This proved that the iron pyrite in the flotation residue was either a different mineral from the iron pyrite in the flotation concentrate or else the oil or some other agent formed a protective coating over the mineral floated. In any case, the proof was sufficient to indicate that most of the iron in the residue had been unaffected by flotation treatment.

Effect of Thickness of Pulp.

The results of laboratory tests indicated that, with a dilution of 1 to 1, bad recoveries would be obtained, with thinner dilutions up to 7 to 1, recoveries would be normal.

Rapid Method of Determining Dilution of Feed on Large Scale.—A number of 50 cc. cylinders were filled up to graduated mark with weighed quantities of water and ore, the latter being average crushed feed from experimental plant.

The pulp in the cylinders was then agitated and allowed to settle for 5 minutes, and the relative number of cubic centimeters of settled feed and of clear water were read off. The results obtained were used as standards for subsequent work.

Tests on the large scale, checking the method against the ordinary one of weighing, showed that it gave good results, the method of taking the dilution being to fill a 100 c. cylinder with pulp out of one of the agitators. A number of large-scale tests proved that the results were not affected by having dilutions ranging from 2 to 1 and 5 to 1, providing the feed was not heavy.

With a feed of over 20 tons per hour it was found advisable to work with a dilution under 3 to 1, owing to the work being adversely affected if the rate of flow of pulp through the machine was too great. Dish vaning tests showed that the quantity of elutriated slime in feed varied from 15 to 20%.

Nature of Water Used.

The following are average analyses of waters that were used for large-scale experiments. One sample was taken while flowing into the Minerals Separation plant, a second sample from the residue pulp after treatment. Analyses were made on clear solutions after filtering:

¹See paper No. 201 of Australasian Institute of Mining Engineers.

	Before treat- ment. Gr. per gal.	After treat- ment. Gr. per gal.
Total solids	35.14	78.26
Loss on ignition.....	13.21	23.91
Calcium oxide	4.27	16.87
Magnesium oxide	10.81	9.25
Sulphur trioxide	3.41	27.75
Copper	nil	nil
Iron	nil	nil
Acidity	neutral	neutral

Analyses indicate that CaSO₄ is dissolved from the ore during treatment.

The following method of testing whether a particular sample of water was suitable for flotation or not may be of interest. A sample of crushed ore was treated in the laboratory machine with the water to be tested by passing it dry into the machine and obtaining the recoveries. A sample of the same ore was then thoroughly wetted with the sample of water and allowed to stand in it for some definite period. The sample was then treated by flotation, and recoveries so obtained were compared with recoveries from the first test.

The following comparative assays of residues from the same crude ore were obtained from a sample of water which was unsuitable, and which was applied in two different ways. The same conditions of treatment were used in both cases:

(a) Sample treated immediately in water. Residue assayed 2.60 dwt. gold, 0.30% copper.

(b) Sample allowed to remain under water for 6 hours and then treated by flotation. Residue assayed 3.09 dwt. gold, 0.67% copper.

Water was found to be neutral, and after agitation with ore still neutral.

Effect of Fine Crushing.

No opportunities were available for finer crushing on the large-scale experimental plant, as tests showed that a screen finer than 50-mesh could not be economically used. Sizing tests on flotation residue produced from ore crushed to 10% on +60-mesh (I. M. M.) indicated that the better the crushing the better would be the recoveries. The crude ore assayed 5.05 dwt. gold, 2.02% copper, and was treated direct by flotation, 1¾ lbs. per ton of eucalyptus being used.

This test showed a marked improvement in recoveries as compared with the best results obtained on this particular class of ore crushed through 50-mesh either in the laboratory or in large-scale plant. The best recoveries with the coarser crushing were 70% gold, 86% copper.

Rand Gold Output.

The Rand gold output in September was 771,000 fine ounces, comparing as follows:

	1916.	1915.	1914.	1913.
January	787,000	714,984	651,000	789,390
February	753,000	476,000	626,000	734,122
March	796,000	753,000	686,000	790,000
April	754,000	741,000	684,000	784,000
May	777,000	763,000	720,000	794,000
June	761,000	755,000	717,000	517,000
July	761,000	770,000	732,000	655,000
August	781,000	778,000	711,000	728,000
September	771,000	776,000	702,000	706,000
October	797,000	733,000	733,000	718,000
November	781,000	781,000	715,000	673,000
December	781,000	781,000	672,000	776,400
Total	8,888,984	8,599,000	9,124,912	

Copper exports from Atlantic ports for week ending Oct. 5 were 3221 tons; since Oct. 1, 1990 tons, against 4627 a year ago.

Efficiency of Air Compressors.

H. E. MacCamy, designer of the MacCamy condensing intercooler, Dooly building, Salt Lake, some time ago prepared a thesis on air-compressor efficiency, from which the following is taken:

There is only one condition under which a compressor can be operated whereby it can furnish the number of cubic feet of air which it was designed to produce, and this condition is the elimination of the moisture from the air.

Kent and other authorities tell us that every cubic foot of saturated air at 82° temperature contains 0.001667 lbs. of water vapor. This means that for every 1000 cu. ft. of air entering the low-pressure cylinder of the compressor, we have 1.667 lbs. of water, and as there are 28 cu. ins. in 1 lb. of water, we have $1.667 \times 28 = 46.67$ cu. ins. of water to be evaporated into steam gas by the heat due to the compression of 25 lbs. gauge, or 40 lbs. absolute pressure attained in the low-pressure cylinder. Any steam table will tell us that 1 cu. in. of water when raised to the temperature of 267° F., which is the temperature due to 25 lbs. gauge, or 40 lbs. absolute pressure, has an expansion of 642 times its volume. Then we must have $642 \times 46.67 = 29,962$ cu. ins., or 17 cu. ft. of steam gas entering the intercooler for every 1000 cu. ft. of air entering the low-pressure cylinder; and unless this steam gas is condensed to water and removed from contact with the air before the air leaves the intercooler and enters the high-pressure cylinder of the compressor, it will cause trouble and expense, as it not only increases the power required to compress the air, but is the cause of carbonizing the oils used to lubricate the cylinders, and continues to follow to the end of the air line, materially reducing the efficiency of the power at the tool or machine where it is used, as water is a poor agent for operating air tools or engines.

The usual way of removing the water or moisture from the air is to establish auxiliary receivers near the end of the line in which to condense and precipitate the water; but the water should have been removed from the air before it entered the high-pressure cylinder, or at least 90% of it. The power wasted compressing steam gas in the high-pressure cylinder would be saved, and the oil used to lubricate the high-pressure cylinder would do its work instead of being carbonized. This carbon sediment finds its way through the receiver and pipe lines into the tools, requiring user to soak them in kerosene or naphtha.

Investigation shows that all trouble with air compressors and air equipment is due to moisture in the air. Even the back pressure, so often found in the low-pressure cylinder, causing the low-pressure side of the compressor to give more trouble than the high-pressure side, is attributable to this cause. The reason for this is that the ratio of the cylinders is such that the high-pressure cylinder cannot receive the expanded air from the low-pressure cylinder when the intercooler fails to reduce the temperature of the air coming from the low-pressure to 60° or lower; for it must be remembered that the temperature of the air from the low-pressure cylinder is about 300°, which will cause an increased expansion, due entirely to moisture in the air raised to that temperature, of 37% in volume, and unless the intercooler reduces this temperature to 60° the moisture cannot be removed from the air. With the ordinary intercooler, when compressor has been working at its maximum for 1 or 2 hours, the temperature of the air entering the high-

pressure cylinder will be about 125°, and the gauge will show from 25 to 30 lbs. pressure; but if the temperature could be lowered to 60°, and maintained at that, the gauge will show a pressure of 3 to 5 lbs. less. This difference in pressure is caused by the inability of the high-pressure cylinder to receive the expanded air, this being wholly due to the steam gas generated from the moisture in the air, which has not been removed by the intercooler.

The increased volume of workable or useful air we would receive from the compressor, if all the water vapor could be removed from the air before it enters the high-pressure cylinder, would be the volume of steam gas generated from the 46.67 cu. ins. of water contained in 1000 cu. ft. of saturated air, figured at the point of condensation. The power in foot-pounds wasted in compressing the steam gas in the high-pressure cylinder would be determined by multiplying the cubic inches of steam gas allowed to enter the high-pressure cylinder by 62.5 lbs. per sq. in., as this is the mean pressure between the 25 lbs. pressure at which the piston begins its stroke and the 100 lbs. pressure at the end of the stroke. It is apparent that the efficiency of a multiple-stage compressor can only be calculated by the amount of water removed from the air in its passage through the intercooler.

Another thing to be remembered is that air is a mechanical mixture, and lowering the temperature alone to the condensing point will not remove the water, for the reason that as soon as the water is removed the dry air will absorb the water if it comes in contact with it again before reaching the high-pressure cylinder. Therefore, the intercooler must be constructed to cool the air to the lowest point attainable with the cooling water available, and make a purely mechanical separation of the air and water.

New Hydro Plant for Sweden.

Arrangements are being made for the utilization of 50,000 hp. through the exploitation of the Folla in Norway. This stream comes from the Trolldheimen mountains, and after a course of about 25 miles joins the Surna, which terminates in the Surendal Fjord. The Folla has no natural regulating basin, not passing through any lake of a size to serve as a reservoir, though it has abundance of water, the catchment area being 347 sq. kilometers. A valley, which is of no special value to anyone, is therefore being flooded to create a lake, having an area of 8 sq. kilometers, by building a wall 30.5 meters high and 648 long. There will be a fall of 300 metres, and at the turbines the power will be 40,000 to 50,000 hp. In addition there are two other falls in the Folla, below the regulating dam, of respectively 7200 and 10,000 hp. The large power station will be situated at the bottom of the Folla valley; a tunnel over 2 miles long and 12 sq. metres section, will lead from the intake to the distributing basin. The energy will be transmitted over 8 miles to Surendalsören, in the vicinity of which the promoter of the scheme controls large lime deposits, which can supply necessary raw material. The manufacture is likely to comprise carbide and cyanamide, an annual production of 25,000 to 30,000 tons being expected. The aggregate cost is calculated at nearly £800,000, of which nearly £350,000 is allocated to the power station, etc., and nearly £75,000 to the electrical plant.

White arsenic is produced in the United States from smelter-flue or bag-house dusts.

Mount Baker Mining District, Washington

MORRIS McCARTY.

The Mt. Baker mining district, situated in the extreme northwestern part of Washington, was first discovered in 1897, or the same year the riches of the Klondike became known to the outside world. The first location of importance known as the Post-Lambert, which was later equipped with a 15-stamp mill, and after producing \$275,000, burned down.

The district, although situated not far away from tide water, is not favorable for the installation of machinery, as it lacks good wagon roads. This defect can and will doubtless be overcome when mines are further developed.

The Cascade range of mountains receive their maximum development at the 49th parallel, which is the international boundary, and Mt. Baker, after which the district is named, is situated in the midst of the district, only 10 miles south of it.

The topography is rough and wild beyond description, and up to an elevation of about 5000 ft., is covered with a dense growth of timber and well carpeted with moss, making prospecting difficult.

The northern portion of the Sierra Nevada mountains of California have not yielded treasures compared with the central California sections of this well-known range, and this is true of the Cascade mountains in Oregon and Washington. Mining engineers have a "cold shoulder" for this area, and not without good cause, as few properties have been developed meriting the name of mine. No really great mines, so far as the writer is aware of, are running from Yreka, Cal., to the international boundary line at the present time.

The prospects in the extreme northwest section of the country are therefore of considerable interest outside of their local importance, and the question as to what, if any influence the maximum development of the range has to do with these ores, is also of some interest.

Having, years ago, prospected close to the international boundary in northeastern Washington and southeastern British Columbia, I familiarized myself more or less with the discoveries made from time to time near the 49th parallel, and have arrived at the conclusion that there is an east-west mineral zone which can be traced from the Atlantic seaboard in the vicinity of Newfoundland to the Pacific ocean. The ores found in this great zone or belt include all of the prominent members of the mineral family, such as iron, copper, nickel, silver and gold.

Numerous individual mines could be cited to support the theory of a cross continental zone and it is barely possible that this fact is closely related to the maximum development of the Cascade mountains near the 49th parallel.

About one year ago, George Wingfield, president of the Goldfield Con., which company it will be remembered made us "millionaire prospectors" a trifle jealous several years ago by paying in one year more than \$7,500,000 in dividends, closed a deal for a controlling interest in the Boundary Red Mountain mine, in the Mt. Baker district, which was already equipped with a Marathon mill. He installed, at great expense, 10 gravity stamps, developed a water power and commenced operations about March 15 of the present year. The mill treats from 50 to 60 tons daily and makes a

saving of upwards of 90% by plain amalgamation, demonstrating the remarkably free nature of the ore. A crosscut tunnel is being driven to tap the ore 500 ft. below the deepest workings, and if the results are as favorable at that depth as at present levels, the intention is to erect a large mill. While no definite figures are given out, the ores are said to average from \$15 to \$20 per ton. The ore body has been proven 800 ft. long with drift continuing in ore.

The Post-Lambert is being equipped with a Lane slow-speed mill, and will soon be ready to run. The ore resembles the property purchased by Mr. Wingfield. Several more properties have power developed and are doing active development.

At the Hammond, which is situated some 15 miles southward from the free milling section of the Mt. Baker district was erected some years ago a 20-stamp mill with auxiliary mills—one a Huntington and the other a Bryan—also, later a cyanide plant was erected but only ran but few days. The property produced, it is said, about \$100,000 and was closed down because the values in the ore could not be saved closely. The ore is a silver-sulphide.

The company has been reorganized with new capital, with the result that George Crerar, M. E., who was connected with the demonstrating plant of the Inspiration Copper Co. at Miami, Ariz., has been chosen to manage the metallurgical end. Mr. Crerar is installing the flotation process and the capacity of the mill will be increased by installing a tube mill. The mine contains large ore bodies and the outlook for making a success of this property is excellent with the flotation process. The ore contains silver-gold, the former predominating.

Stone and Webster own a power plant near the mine where the Nooksack river falls 105 feet. The mine, however, possesses its own power plant, and because of the numerous water powers and timber facilities, the conditions for doing cheap mining are most excellent.

The Mt. Baker district, except for heavy machinery (some sections are accessible to it), is easy of access from Bellingham, which is the county seat of Whatcom county, situated on one of the really great harbors of the world. The county enjoys the distinction of being the most northwesterly county in the United States and the richest in natural resources on the Pacific coast.

Calcium Chloride Production.—Calcium chloride is made from natural brines in the Saginaw valley in Michigan, in the Ohio valley in Ohio and West Virginia, and in the Kanawha valley, W. Va. Thus practically every constituent in these brines is saved and turned into profit. Calcium chloride is manufactured at Mount Pleasant and Saginaw, Mich.; Pomeroy, Ohio; and Mason, Hartford, and Malden, W. Va. Statistics of production of calcium chloride from natural brines have been collected by the Geological Survey since 1909. Large quantities of calcium chloride formerly wasted in the manufacture of soda, the source of which is different from that considered in this report, are now being used in part, and it is to be hoped that new uses for what is still wasted may soon be found.

Large Capacity Flotation in Small Space.

In concentrating mills there is frequently little space allowed for the machines, and it is desirable to have as great efficiency per unit as possible. Among the recent improvements in concentrators of the flotation type is one which embodies this feature. It also possesses another advantage, in that the ore particles which cling to the countless air bubbles are removed so quickly after reaching the top of the tank that they are hardly exposed to the free air, which would cause the bubbles to break and the concentrates to sink. The units, of which two are shown in the drawing, are designed to operate in series.

Referring to the drawing: Each tank is first filled with water. Power is applied by means of a driving belt and pulley to the vertical shaft, and the dasher in the cylindrical tub in the bottom of the tank is revolved. The pulp or equivalent ore material is fed in at the bottom through a pipe, while air is supplied continuously through another pipe as shown.

The ore, upon arriving in the tub, is agitated by the dasher and the air is broken up into very fine par-

FLOTATION CONCENTRATOR WITH LARGE CAPACITY.

ticles which permeate the ore mass. In this way, any fine particles of ore which have a tendency to float, adhere to the air bubbles and are carried upward by them. The particles of ore thus floated are the concentrates. The gangue, being unable to float, and yet being agitated continuously by the dasher, is carried over the sharp upper edge of the tub and floats or creeps downward around the tub and out through a pipe, through which it is introduced to the next successive tank.

The particles of ore, floated as above described, by the minute air bubbles, are carried up through various baffle floors and reach the top of the tank. They are carried over the sharp upper edge of the wall, arrive in the drain boxes and are carried off through the discharge spout. The baffle floors, being immovable, serve to render the liquid comparatively quiescent, or, in other words, they prevent further disturbance of the ore particles after they are properly floated. In order to render this action effective, more than one floor is provided.

The concentrates, which carry with them more or less gangue or crude material, next pass through another machine of the type just described, and in this way still further refinement may be effected.

Automatic Handling of Cars to Tipple.

More or less trouble and expense are incurred in running mine cars onto the tippie or dump. Manual labor is employed in many mines for this purpose, the loaded cars being pushed onto the tippie and the empties gotten away to the cross-over in the same manner, with many delays. Archibald Ferguson of Roscoe, Pa., in a patent (No. 1,187,825) recently granted, seeks to overcome the lost motion and effort by a combination of a gravity system and a series of car stops operated automatically by the movement of the tippie as it dumps each car.

The track to the tippie is arranged on a down-grade. The tippie track is level and there is a section of track beyond the tippie which is slightly up-grade. After dumping, the empties are run out onto this farther section through a spring point switch and then back by a cross-over to the return track, which is down-grade. The empty cars are therefore carried back past the tippie by gravity to a point where they can be removed by a locomotive.

The novel feature lies in the car stops, one being shown by the sketch herewith. Several of these stops are located at points on the down-grade approach to the tippie. Normally, when in the upright position, the

AUTOMATIC CAR STOP.

stop holds the car stationary. When the car on the tippie is dumped, the tippie in falling back into place operates a series of levers and throws the stops all down. The car nearest the tippie runs onto the tippie, and the stops are returned to normal. But in the meantime the cars back along the line have all moved up one stop. In this manner, a whole train of cars can be backed onto the down-grade portion and left to themselves, feeding onto the tippie automatically as fast as it dumps and removes the empty cars.

China to Have Tin-Smelting Plant.—A tin-concentrating and smelting plant for the An-Yuan mines in Hunan Province, southern China, is shortly to be placed in commission by the Wah Chang Mining & Smelting Co., Ltd., which will offer this product for sale in the United States. The company has offices in the Woolworth building, New York, and agencies in Europe. These mines are in the Ichanghsien district and contain both oxide and sulphide ores in chimneys in limestone, marmorized by granite and intruded by a later granite dike along the course of which the ore chimneys are found.

The most refractory clays are those containing an excess of alumina.

Making Motor Trucks Pay.

Whether the haul be long or short, the use of motor trucks can be made to pay just as good returns

stronger in this field, a new type of body is being widely used, as is also a special kind of loader. Both are designed to save practically all of the time and manual labor at each end of the trip; in other words,

TWO-WAY DUMP BODIES ON MOTOR TRUCK AND TRAILER.

in the transportation of ore as in that of any other raw material. After all, time is the great element. In these days of rapid-moving trucks and trailers of large capacity, and ability to negotiate almost any

to give the truck an opportunity to be actually earning money every hour that it is on the job.

The Lee two-way dump body is mounted on any type of truck or trailer in the manner illustrated. It

LEE LOADER AT WORK.

hills or kinds of going, the horse is in no sense better equipped to compete with trucks in the mine country than he was with Pershing's trucks in Mexico.

To make the position of the motor truck even

dumps to either side, clear of the wheels. It is particularly adapted for loading direct onto the car from a raised platform, having inclines so that the truck can climb up to a level with the top of the cars. The

dump body rolls outward and over at the same time so that the load can be distributed over the car bottom.

These bodies can be operated without the use of mechanical power, and they discharge their load in less than half a minute. One man easily attends to this operation, without the use of cranks, handwheels or winches, the hang of the body being such that the weight of the load furnishes the principal power for dumping.

A combination unit has also been designed for hauling cement in bags or barrels, lumber, timbers and other materials used about the mine.

At the loading end, the Lee loader can be used to advantage. It travels on low wheels from point to point along the ore storage bins. It consists of a hopper-like arrangement mounted on a tower just high enough to clear the truck body. This hopper is loaded while the truck is away with a load. When the truck draws up beside the loader the hopper is rolled outward and over as shown, loading the truck with scarcely a moment's delay.

Obviously, the shorter the haul and the more frequent the trips of the truck, as in cases where the mine is near the railroad or mill, the greater the economical advantage of the loader, as in that case the loading time is a greater factor.

Gold Mining in the Boise Basin, Idaho.

The Boise Basin of western Idaho has always been primarily a gold placer region, and for a decade after the discovery of gold there, late in 1862, it is credited with an annual placer production of one to five million dollars. In later years the yield has fluctuated greatly, but in 1912, 1913, and 1914 it still amounted to approximately half a million dollars annually. Many of the veins from which the placers derived their gold were located in the early days, and in recent years they have received increasing attention. To meet the many demands for information concerning these lodes, the U. S. Geological Survey has just published a reconnaissance report on the region as Bulletin 640-E.

According to this report the depression known as the Boise Basin has resulted from the sinking of a fault block 15 miles long and 12 miles wide. The region lies within a great area of granite that extends over more than 20,000 sq. miles, the surface of a mass known as the Idaho batholith, which is believed to be of late Cretaceous or early Tertiary age. Porphyritic dike rocks in considerable variety were intruded into the granite and afterward the metalliferous veins were formed. The veins occupy zones of close-spaced fracturing in granite, and as the maximum depth to which mining has extended is not great most of the ores now mined are somewhat oxidized.

The principal primary ore minerals are native gold, pyrite, galena, sphalerite, chalcopryrite, stibnite, and tetrahedrite. The secondary minerals are cerussite, chalcocite, malachite, and native copper. Only the precious metals are now recovered from these ores, but as the mines go deeper the ores become increasingly base, and in the near future lead, copper, and possibly zinc will doubtless be saved. Probably less than 50% of the gold can now be saved by amalgamation.

It is of interest to note the widespread occurrence in the placer gravels of the Boise Basin of monazite, which is extensively used in the manufacture of gas

mantles. This source of supply, however, is not now utilized. An unidentified radium-bearing mineral also occurs sparingly in the gravels at one locality.

Opposed Plate Crusher.

A combined compressive and rubbing action between massive sets of plates, one stationary and one reciprocal, is brought about in the ore crusher shown in the accompanying sectional and elevation views. It is the invention of James W. Boileau of Chicago, Ill.

It will be seen that the interior sides of the crusher consist of slanting face plates, with corrugated sur-

OPPOSED PLATE CRUSHER—CROSS-SECTION.

faces and means at the bottom for slight adjustment of the angle. Two sectional corrugated plates are set up in the middle of the machine, in such manner that they are given an up-and-down movement when the driving pulley is turned. This motion is imparted by a walking beam and rock shaft shown in both drawings.

Not only is this motion of the central plates a reciprocal one, but, through the agency of knuckles

OPPOSED PLATE CRUSHER—SIDE ELEVATION.

on the upper shaft, the upper ends of the plates move in a curved path, while the lower ends are moving in practically a vertical plane. In this way both a compressive and a rubbing action are secured. The corrugations get finer and finer toward the bottom of the plates, as the ore is more and more finely ground. The ore finally falls through the narrow openings at the bottom of the plates.

What the Mining Companies are Doing

Kerr Lake Mining Co., Ontario.

The annual report of the company for the year ending Aug. 31, 1916, shows the gross production from all ores to have been 2,433,893 ozs. of silver, at a mining cost of 889-100 cts. per ounce; 58,850 tons of rock was hoisted at a cost of \$3.68 per ton. Total costs per ounce were 25¼ cts.

Cost of production and development expenses are given as follows:

Stopping	\$ 18,909.87
Development	46,443.75
Power, light and heat.....	24,092.18
Ore sorting and jigging.....	14,426.42
Tramming	21,655.54
Hoisting	8,691.90
Timbering	18,912.62
Pumping	3,416.44
Drills and steel.....	8,345.99
Mine expense	11,557.36
Repairs to plant and buildings.....	1,403.76
Stable expense	4,250.81
Office expense	5,092.90
Surface maintenance	8,549.04
General expense	2,314.57
Taxes	17,583.57
Boarding house	901.85
Total	\$216,548.57
Other expenses—	
Shipment, treatment and other charges.....	\$ 203,627.27
Administration and general expense.....	13,672.20
Amount written off cost of property.....	24,589.35
Exploration outside properties.....	14,070.48
Total	\$ 472,507.87
Balance transferred to profit and loss account.....	\$13,701.90
	\$1,286,209.77

Colorado Fuel & Iron Co.

The 21th annual report of the company, covering the year ended June 30, 1916, has just been issued. A brief summary is here given:

Income Account—

Gross earnings from operation.....	\$25,626,605.54
Operation and management	21,280,519.74
	\$ 4,346,085.80
Net earnings from operation.....	492,606.83
Income from securities and interest....	132,984.95
	\$4,971,076.68
Deduct: Bond interest and taxes.....	\$ 2,011,958.73
Taxes	348,888.92
	2,360,847.65
Surplus over fixed charges, as above	\$2,610,229.03
Less: Provision for sinking funds, etc..	\$ 184,088.51
Insurance and personal injury.....	58,000.00
Crystal River R. R. Co. traffic contract guaranty	15,000.00
Prospecting	6,969.63
Equipment renewal	145,000.00
	409,058.14
Surplus after deducting sinking funds, etc.....	\$2,201,170.89
Out of which was declared a dividend of 30% on preferred stock	600,000.00
Surplus after deducting sinking funds, preferred stock dividend, etc., carried to the credit of profit and loss.....	\$1,601,170.89
General profit and loss account—	
By balance at credit June 30, 1915.....	\$3,376,280.86
By surplus for year ended June 30, 1916	1,601,170.89
To customers' accounts charged off.....	\$ 22,110.20
To bond premium	3,823.00
To depreciation on equipment charged off	19,755.00
To various adjustments during the year	12,895.12
By various adjustments during the year	3,258.85
To balance	4,922,127.28
	\$4,980,710.60
By balance to credit of profit and loss June 30, 1916, as per balance sheet	\$4,922,127.28

Round Mountain Co., Nev.

Placer operations of the Round Mountain Mining Co. during the period from July 13, 1915, to July 1, 1916, resulted as follows:

Period.	Value recovered.	Cost.	Realization.
July 13, 1915, to Nov. 1, 1915....	\$36,413.70	\$11,058.18	\$25,355.52
Nov. 1, 1915, to March 1, 1916..	9,203.62	5,397.32	3,806.30
March 1, 1916, to July, 1916....	48,176.53	27,897.58	20,278.95

Alaska Treadwell Co.

Returns for the month of August are reported by the Alaska Treadwell Gold Mining Co., as follows:

Tons ore crushed.....	24,696
Tons concentrate saved.....	784.58
Estimated gross value of free gold.....	\$11,825.34
Estimated gross value of concentrate.....	63,582.83
Estimated gross value of base bullion.....	2,787.46
Estimated gross total production.....	\$78,195.63
Estimated gross total realizable value.....	\$77,413.68
Operating expenses	44,416.66
Estimated operating profit.....	\$32,997.02
Construction expenses, etc.....	17,583.57
Estimated net profit.....	\$15,413.45
Other income	11,281.07
Yield per ton of ore milled.....	\$3.16

Tonopah Mining Co.

The combined income and surplus account of the Tonopah Mining Co. and the Desert Power & Mill Co. for the quarter ending Aug. 31, 1916, shows as follows:

Gross value of ore milled.....	\$ 336,287.37
Metal losses in milling and refining.....	26,257.10
Gross value of mill products.....	\$ 310,030.27
Mining, milling, marketing and general expenses..	212,982.32
Net earnings for quarter.....	\$ 97,047.95
Miscellaneous income	40,970.15
	\$ 138,018.10
Exploration expense	15,305.17
Net income for quarter.....	\$ 122,712.93
Quick Assets—	
Cash on hand Aug. 31, 1916.....	\$ 36,172.24
Bonds purchased	1,019,831.25
Certificate of deposit.....	25,000.00
Silver bullion stored at 50 cts. per oz.....	431,010.95
	\$1,512,014.44
Deduct dividend payable Oct. 21, 1916.....	150,000.00
	\$1,362,014.44

Calumet & Hecla Outputs.

The September and 9 months' outputs of the Calumet & Hecla and subsidiary companies compare as follows (in pounds of copper):

	1916.			9 months.	
	September.	August.	July.	1916.	1915.
Ahmeek	2,309,955	2,173,439	1,741,097	17,685,686	15,000,000
Allouez	896,184	870,758	744,624	7,649,473	7,000,000
Cal. & Hecla..	6,257,447	6,603,418	6,172,908	57,191,355	52,000,000
Centennial	160,800	207,486	190,262	1,828,245	1,700,000
Isle Royale	1,010,723	1,199,162	980,574	9,226,225	6,700,000
La Salle	119,269	109,032	93,580	954,489
Osceola	1,700,522	1,625,498	1,818,241	14,935,700	14,000,000
Superior	230,582	192,463	183,020	2,354,530	2,900,000
Tamarack	512,666	513,441	476,652	4,949,184
White Pine	385,577	426,152	277,941	3,280,142
Total	13,573,725	13,920,849	12,678,899	120,055,029

Franklin Mining Co.

The Franklin Mining Co. has been able to reduce its operating costs from 21 cts. per pound of copper last January to a present cost of 15½ cts.

On present price of copper and a monthly output of about 270,000 lbs. of copper, profits now average over \$30,000 monthly, which is accumulating for working capital. The last of the company's notes was paid recently and its books now stand clear of floating indebtedness.

The output by months thus far this year follows:

	Lbs. refined copper.		Lbs. refined copper.
January	200,000	May	285,000
February	233,000	June	265,000
March	266,000	July	275,000
April	194,000	August	265,000

Production for first 8 months exceeds by 665,031 lbs. that for the entire 1915 calendar year. Output for the present year

has been sold for better than 25 cts. a pound, which compares with average price of 19.83 cts. in 1915.

Tonopah Belmont Co.

The combined condensed statement of operations of the Tonopah Belmont Development Co. and the Belmont Milling Co. for the quarter ending Aug. 31, 1916, shows as follows:

Received and receivable for ore, bullion, etc.....	\$ 634,923.49
Mining, milling and administration expenses.....	327,789.79
Net earnings for quarter.....	\$ 307,133.70
Miscellaneous income.....	7,278.01
Total net income for 3 mos. ended Aug. 31, 1916.	\$ 314,411.71
Available resources, August 31, 1916—	
Due from smelters and silver stored at 50 cts. per oz.	\$ 618,355.81
Due from others.....	12,630.43
Loans on collateral.....	250,000.00
Cash in banks.....	507,147.34
	\$1,388,133.58

Miscellaneous Company Reports.

The Nipissing Mines Co., Ltd., as of Oct. 2, 1916, had cash in bank, \$1,280,957; value of bullion and ore in transit and at smelters, \$487,730; value of ore on hand and in process and bullion ready for shipment, \$159,752; total, \$2,228,440.

Mohawk Mining Co.'s earnings for the last 6 months of 1916 will be in excess of \$1,000,000. In September the yield was 19.67 lbs. of copper per ton treated. Copper production was 1,145,762 lbs., as compared with 1,019,460 lbs. in August.

The operating companies of the La Rose Con. Mines Co. as of Sept. 30, 1916, had cash surplus \$806,717; ore in transit and at smelters, and ore sacked at mine ready for shipment, \$69,421; less current liabilities, \$38,071; leaving balance of current assets, \$838,068.

Bingham Coalition Mines Co. has filed notice with the Utah secretary of state that the capital of the concern has been raised from \$1,000,000 to \$1,500,000. The company is incorporated under the laws of Maine, but Utah laws require foreign concerns to conform to laws of that state.

Profits of the Arizona Commercial Co. for the first 8 months of this year have averaged \$47,000 monthly, or at the rate of \$564,000, or \$2.10 per share, per annum. With an increase in output early next year dividends of 50 cts. quarterly would seem a natural expectation as the company has a comfortable working capital of about \$600,000 and no large construction expenses ahead.

Work on new mill of the Butte-Detroit Mining Co. is completed and workmen laid off. Orders have been placed for machinery and equipment of a flotation plant patterned after that at mill of the Butte & Superior. As soon as this is installed sinking at the Ophir mine will be resumed. Work at mine was suspended until mill was completed. Ophir mill is now in shape to handle zinc ores.

The Atlantic Mines Co., which 3 years ago took over La France Copper Co. property, has been dissolved and all the property with exception of cash on hand will be offered for sale at public auction in Butte Nov. 1, following which a dividend in liquidation will be distributed. The Anaconda Co. has offered a price for the property which will return Atlantic Mines Co. stockholders the \$250,000 cash originally in company's treasury when operations started, and a sum equal to the par value of the stock—\$10—together with 8% interest per annum, a total of about \$12.50 per share.

Present earnings of the Shannon Copper Co. are the largest in the history of the company, with profits amounting to around \$100,000 monthly, or at the rate of \$4 per share. For the first 9 months of this year profits were \$625,000, which is more than sufficient to meet the full year's dividend requirements at present regular rate with extra. The treasury is now in a strong position with about \$1,200,000 net quick assets so that practically all earnings can now be declared in dividends. At the present time there remains in the hands of the public only \$169,000 Shannon Arizona Railway bonds out of an original issue of \$600,000. Production is sold well ahead, a portion into next April at approximately 27 cts. per pound, which assures a continuance of present large profits

for 6 months at least. The highest price yet received by the company was 29¼ cts. a pound for 625,000 lbs. sold last May for August delivery which was a "special" transaction.

Stanley Dexter, referee in bankruptcy, has been enjoined from confirming the sale of the Ohio Copper property to the bondholders' committee. Sale actually took place 6 weeks ago, but a stay was granted at the request of the North American Liquidation Co. in order that plans might be prepared giving stockholders opportunity to rehabilitate the company. Further decisions regarding the sale by the referee were held up by the Federal Court, on application of a second group of stockholders, in which the Heinzes have an interest. Their contention was that referee had no right to offer at auction the "right of redemption," which sold for \$40,000.

Sales of 1,500,000 lbs. of copper have been made recently by the Mass Con. Mining Co. at prices ranging from 27 to 28½ cts. a pound, according to delivery. With this sale the company is sold fairly well ahead into next year with some copper still available for nearby delivery. Operations for the past 4 months show a profit in excess of \$200,000 over and above all construction and improvement expenses, a sum sufficient to pay 6 months' dividends at the rate of \$4 per annum. Production for the past 9 months exceed the output for the entire 1915 calendar year, which amounted to 4,638,452 lbs. refined copper, a 5,000,000-lb. production being estimated for the present year.

At the present time Chino Copper Co. is producing at the rate of close to 80,000,000 lbs. of copper per annum. With copper at 27 cts. profits should be close to \$14,000,000, or \$16 a share on 870,000 shares. Selling at \$55 per share, the company may be said to be earning 30% on the market price of its stock. So long as the dividend rate remains as at present, \$9 per share, the purchaser of stock at 55 has an income return of 16%. What action the directors will take at the December meeting as to the size of the regular quarterly dividend is problematical, but it is positive that a declaration of the regular \$1.25 per share will be added to the same as in September when an extra of \$1 was paid.

While Hancock Con. is not yet out of debt and has no accumulated treasury balance, production is profitable, and as rapidly as more men can be added to the present working force of 400, production will show a substantial increase. The rock coming from No. 7 Quincy is all of a standard grade of excellence and this month the tonnage will be over 8000. All this goes to the Quincy mill and the Quincy smelter for treatment. From No. 2, 16,000 tons of rock will be treated this month and this is handled in the Point Mills head of the Hancock Co. and smelted at the Calumet & Hecla plant at Hubbell. In both workings the physical condition is decidedly better than at any time since the present work was undertaken.

The American Zinc, Lead & Smelting Co. has increased its retort capacity by the addition of another "block" to the Granby Mining & Smelting Co.'s equipment. This would add about 800 retorts and, assuming an average yield of 3½ tons of spelter per retort per annum, swelling the company's total production by about 2800 tons of spelter a year. The absorption of the Granby property added materially to the strength of the American Zinc, Lead & Smelting Co.'s position among the zinc producers of the country. This is particularly true because of the fact that the American Zinc Co. can now enter the market as a seller of any and all grades of zinc, from ordinary prime western up to the intermediates and high grades.

Earnings of the U. S. Smelting Co. for September are estimated to have been close to 100% ahead of July and August, or at the rate of between \$800,000 and \$900,000, as compared with a low-water mark of close to \$400,000 for the two summer months. The improvement in earnings is due mainly to the advanced prices as compared with 60 and 90 days ago of silver, lead, copper and spelter. As U. S. Smelting is more than 50% a custom smelting proposition it benefits very substantially by a rising metal market. Although no inclusion is being made of profits from Mexican properties it is expected that the final quarter will show reasonable returns from across the border, though it is any one's guess when conditions there will approach the normal.

Subscription Notice.

Owing to the extraordinary increase in the cost of paper (more than double) used in printing the domestic edition of Mining and Engineering World as well as the increased cost in every department of printing it has been found necessary to increase the subscription price to \$5.00 per annum.

United States to Output Two Billion Pounds of Copper in 1916.

There is every reason to believe that the output of copper in the United States this year will exceed the 2,000,000,000-lb. mark for the first time, and it is expected that domestic consumption will take care of more than half of this. Estimates, however, indicate that exports will not reach the previous record of 840,000,000 lbs. in 1913. This would indicate domestic needs rather than export demand is the principal factor in keeping copper metal prices in the vicinity of 28 cts.

The United States refinery output for a series of years follows:

	Output, lbs.	Inc., lbs.	Increase, per cent.
1916 (est.)	2,000,000,000	453,400,000	28
1915	1,647,000,000	113,219,000	7.4
1914	1,533,781,000	*88,669,829	*5.4
1913	1,622,450,829	40,530,542	2.6
1912	1,581,920,287	149,981,949	10.4
1911	1,431,938,338	*20,183,782	*1.4
1910	1,452,122,120	46,719,064	3.3

*Decrease.

It is of interest to compare in tabular form the United States consumption and exports of copper for a series of years:

	U. S. con- sumption lbs.	Exports, lbs.
1916 (est.)	1,220,000,000	750,000,000
1915	580,000,000	596,000,000
1914	653,000,000	795,000,000
1913	767,000,000	810,000,000
1912	819,000,000	725,000,000

Reinforced Concrete in Mining Operations.

There is no doubt that the ordinary mining engineer, while more or less familiar with his own particular subject, is considerably behind his colleagues in other fields in regard to general engineering applications and developments. This is undoubtedly due to the isolation of the average mining engineer, principally on account of location. This condition of affairs results in a general lag in the application of many modern developments to mining operations.

On the other hand, when such developments are

brought to the attention of the mining world, there is no class of people more eager to adopt any and all improvements of merit, and none more open to a clear appreciation of the situation.

This applies with particular force to concrete and reinforced concrete in their utilization in mining developments. The production of concrete has increased many fold within the last decade, and not only has the quality become superior, but methods and ease of installation are also improved and the cost has diminished almost in the same measure. Owing to these developments, concrete has been substituted in many cases where timber and brick and iron and steel were formerly used, and with gratifying results both from an operating and first cost point of view.

Can We Look Into the Rock?

The rocks of the universe are like a sealed book, but will disclose the contents when the key is once possessed, and this can only be acquired by the active, conscientious and carefully guided mind, keenly observant, always alert to deduce from his observations the minutest law of nature, even though it might seem to others insignificant. Deductions carefully made from nature's consistent showings, refined by well applied comparisons and all brought together into a comprehensive completeness, will bring into vision the key—the possession of which will unfold the intricacies of nature's composite work, whereby we may study and realize the beauties and profit which she spreads before all.

The acquisition is not reserved for any one man, even though he be a Humboldt, or one of the many bright minds who have and are following him, but each who possesses the patience, perception, and method, may share in the honor which is the reward for conscientious work among the rocks, one of the greatest gifts of mankind from nature's bequest.

Cheap Mining and Dividend Payers.

There probably does not exist a mine manager or superintendent who is not desirous of attaining low-cost mine operations. It is a laudable desire and one that proves that he has other than merely a salary compensation in view.

In order that cheap mining may be accomplished, it is necessary that physical and economic conditions should be such that work can actually be done for little money. While some mine superintendents do work as cheaply as it can be done under existing conditions, yet it is not accomplished at a figure that attracts attention. It may be cheap, however, as compared with the cost of similar work being done elsewhere.

Another superintendent may get his costs so low as to seem almost impossible of accomplishment, but yet his mine is paying no profits for the reason that the ore is too low grade. It will generally be found that the good dividend paying property is the one that

accords the mine manager the greatest opportunity for praise.

Fluctuations in silver have some peculiar effects upon trade of China, according to Consul Sammons of Shanghai. At low silver prices the Chinese export trade is not flourishing, as then the Chinese importer and foreign exporter do not seem able to agree upon fair price of goods. It is an excellent opportunity for the importer to buy goods when gold value of silver is low, and resell on a gold basis to foreign consumer. But Chinese dealers are well posted through their system of guilds which flourish all over the country and distribute information somewhat similar to our commercial organizations. They, therefore, learn the true value of their goods at low silver prices and offer the goods at just about the amount of silver the foreign importer ought to give and have a fair profit. When gold value of silver begins to rise, the foreign importer is more anxious to close before silver value becomes so high as to leave him little profit, while the Chinese exporter wants to sell before the silver value becomes so high that amount of silver actually received by him shrinks more and more. Under these conditions transactions are concluded with more diligence, turnovers are larger and exports materially increase.

Wherever possible the railroads have granted a special rate covering the period of the convention of the American Mining Congress, to be held at Chicago, Nov. 13 to 17. In Western Passenger Association territory where the rates approximate 2 cts. a mile, no further concessions are made to any gatherings. From California and Pacific Coast common points the information is given out that the 9-months tourist rate of one and one-third fares to Chicago and return applies for the period of the sessions of the American Mining Congress. The Central Passenger Association which covers common points in Illinois, Indiana, Ohio, Pennsylvania, West Virginia, Michigan, Eastern Missouri, Western New York, has made a 2 ct. rate each way. These tickets will be sold Nov. 11, 12 and 13, and have a return limit to Nov. 20. Holders must reach original starting point before midnight of Nov. 20.

England has been increasing her zinc smelting capacity during the past year and when construction now under way is completed, that country will be in a position to produce spelter amounting to about 85,000 tons annually. While the large zinc mines of Australia are controlled in England, the ore has been smelted in German-owned smelters. With the breaking out of the war this ceased and the major portion of the Australian zinc output has been coming to the United States, while some has been sent to Japan. A zinc smelting industry has also been building up in France.

The Lake Superior copper district is not the only mining section in the country that is suffering from lack of men, as the same condition exists in nearly all the larger camps in this country. Agents from various districts visit the Lake copper country nearly every month in search of men and many of the camps of the western hemisphere have recruited their working forces in times past from the Michigan mines.

PERSONAL.

R. B. Brinsmade is at Pueblo, Mex.

B. M. Sparke of Spokane, Wash., was in Helena, Mont., recently.

Carl H. Beal has joined the Bureau of Mines in the petroleum division.

B. L. Thane, manager of the Alaska Gold Mines Co., is in New York city.

Samuel L. Boyer is inspecting mining properties at Drummond, Mont.

George E. Bailey, mining engineer, Republic, Wash., is at Trail, B. C., on professional work.

J. V. Pohlman recently inspected mining properties in the Coeur d'Alene district, Idaho.

V. E. Lednicky has been appointed chief geologist of the Philippine Bureau of Science.

A. J. Devlin will act as temporary manager of the Empire Copper Co., in Custer county, Idaho.

Dorchester Mapes of Chicago has assumed the management of the Rambler mine near Laramie, Wyo.

D. Foster Hewitt of the U. S. Geological Survey has completed an examination of vanadium properties in Peru.

George P. Mims, a mine operator in the Republic section, Washington, has been appointed postmaster at Medford, Ore.

J. Cleveland Haas, mining engineer, Spokane, Wash., has been in Duluth, Minn., recently in the interest of British Columbia properties.

Frank W. Hopkins, vice-president of the Traylor Engineering & Mfg. Co., Allentown, Pa., has returned from a western business trip.

Kirby Thomas, mining engineer, New York city, has been engaged in an investigation of zinc and other mineral resources of the south.

D. D. Fraser, who has been at Butte, Mont., has joined the engineering staff of the Highland Valley Mining & Development Co. at Ashcroft, B. C.

Charles C. Newton, manager of the Consolidated Interstate-Callahan Mining Co.'s properties at Wallace, Idaho, was in Boise on business last week.

B. F. Tibby, who has been in mining engineering work several years, with offices in Salt Lake City, has taken a position with the Bureau of Mines, Washington, D. C.

Oscar G. Engelder, recently general manager of the Miniera di Rosas at Rosas, Sardinia, who has been spending a few weeks at Houghton, Mich., has gone to Jerome, Ariz.

Preston Locke has been appointed northwest manager for the American Smelting & Refining Co., with headquarters in Spokane. He was formerly in the New York office of the company.

Prof. F. W. Sperr, head of the mining department of the Michigan College of Mines, read a paper on "Metal Mine Accidents and Their Prevention," before the National Safety Council at Detroit.

R. C. Allen of Ann Arbor, state geologist for Michigan, spent a few days at Houghton to furnish information for the State Tax Commission in a disputed case of valuation between two townships.

R. L. Agassiz, president of the Calumet & Hecla Co., who, with General Manager Jas. MacNaughton, was hunting with Wm. E. Corey in Montana, has been at Calumet, Mich., on official business for a few days.

Will L. Clark, manager of the United Verde Copper Co., Jerome, Ariz., has resigned and has been succeeded by Robert E. Tally, who has for 8 years been superintendent of mines for the company. Mr. Clark was connected with Senator Clark's property since 1889, and since 1904 as manager. It is understood he will give his attention to properties in which he is interested. He is a member of the American Institute of Mining Engineers, the Metallurgical Society of America, American Mining Congress, Archaeological Society of Arizona, American Historical Society and National Geographic Society. At the present time he is a director of the State Taxpayers' League of Arizona. He has been president and treasurer of the Verde Tunnel and Smelter Railroad Co., Clarkdale Improvement Co., Upper Verde Public Utilities Co., Mogollon Lumber and Timber Co., and Jerome Power Co., all United Verde subsidiaries.

OBITUARY.

Thomas M. Brennan, manager of the Gold Hunter Mining & Smelting Co., passed away at Mullan, Idaho, Oct. 15 at the age of 39 years, from an attack of pneumonia. He was one of the most promising and popular young engineers in the northwest and his death is sincerely mourned.

Lewis M. Jones, of Pittsburgh, Pa., mining engineer and expert rescuer of the bureau, was killed Oct. 20 while directing the rescue work at a mine explosion at the mine of the Jamison Coal & Coke Co., Barraekville, W. Va., a few miles from Fairmont. Mr. Jones was born in Cleveland, Ohio, and took up his residence in Pittsburgh after he entered the employ of the Bureau of Mines, Feb. 15, 1909. He was a graduate of the Columbia School of Mines, New York city, and was an honor man in his studies. He leaves a wife and one child.

"The death of Mr. Jones is a heavy blow to the Bureau of Mines," said Van. H. Manning. "He was a mining engineer of exceptional ability and was perhaps the best man we had in directing rescue work at disasters. Under the chief mining engineer of the bureau, Mr. Jones had charge of the experimental mine of the bureau at Bruceton, Pa., a few miles outside of Pittsburgh and in this capacity developed many safeguards that are not only saving life in the coal mines today but will be instrumental in the saving of thousands of lives in the future."

SCHOOLS AND SOCIETIES.

Colorado Scientific Society.—At its recent meeting in Denver the abolition of the apex law and extralateral rights were discussed. The speakers included Geo. E. Collins, E. C. Stimson, Henry May and George Manley, all but the latter favoring abolition.

The Institute of Metals.—The officers elected for the coming year at the annual meeting of the American Institute of Metals in Cleveland are as follows: President, Jessie L. Jones, Westinghouse Electric & Mfg. Co., Pittsburgh, Pa.; secretary, W. M. Corse, Titanium Alloy Mfg. Co., Buffalo, N. Y.; senior vice-president, George C. Stone, New Jersey Zinc Co., New York; vice-presidents, R. S. B. Wallace, National Cash Register Co., Dayton, Ohio; William B. Price, Scovill Manufacturing Co., Waterbury, Conn.; George K. Burgess, Bureau of Standards, Washington, D. C.; deCourcy Browne, Goldschmidt Thermit Co., New York city; Harold J. Roast, the James Robertson Co., Ltd., Montreal, Que.; J. P. Salter, Ohio Brass Co., Mansfield, Ohio; F. H. Schütz, H. Mueller Manufacturing Co., Decatur, Ill.; W. A. Cowan, National Lead Co., New York; H. S. Gulick, More-Jones Brass & Metal Co., St. Louis, Mo.

TRADE PUBLICATIONS.

Drill Steel. A. Milne & Co., Chicago. Catalog A-1915; pp. 16.

This catalog gives weights, dimensions, prices per pound, etc., for different kinds and grades of steel for drill bits. The information is all in tabulated form and is accompanied with a leaflet showing sectional views of the company's FJAB steels.

Oil and Gasoline Storage. Wayne Oil Tank & Pump Co., Fort Wayne, Ind. Booklet; pp. 24; illustrated.

An account is often desired of the oil being drawn from tanks at the mine or plant, more accurate than can be obtained by the common method of drawing from a faucet into a measure. The device here described is for drawing the oil from the tank by a pump device arranged so that each stroke will bring a specified and known quantity.

Barometric Steam Condensers. Mesta Machine Co., Pittsburgh, Pa. Bulletin R; pp. 8; illustrated.

Though the major points in the operation and construction of this company's condenser are brought out the text is more particularly devoted to the practice of installing and using steam condensers. There is considerable discussion, bringing out the saving possible to be obtained by running condensing rather than non-condensing. A curve is reproduced showing the saving to be had per 1000 engine horsepower operating 300 days per year and 24 hours per day, with coals varying from \$1 to \$3 per ton.

Wire and Manila Rope and Fixtures. Waterbury Co. Three catalogs; pp. 99, 23 and 31; illustrated.

A separate card is included giving the approximate strength and weight of different grades and sizes of manila rope, with prices for the same included. In the first mentioned catalog an attempt has been made to discuss the different structures of wire rope. Illustrations showing this are given and the uses, properties, etc., of the different kinds are considered. The other two catalogs are somewhat similar but views from the field are shown bringing out the practical application of different kinds of rope. The latter catalogs are confined to considering a smaller line of ropes and deal more with the application of the same.

INDUSTRIAL AND TRADE NOTES.

S. V. Trent, who controls the Trent Engineering & Machinery Co., Salt Lake, Utah, has opened offices in Dooly building, that city.

George A. Muir has been placed at the head of the mining machinery department of the Mine and Smelter Supply Co., Denver, Colo.

Burt B. Brewster, who formerly represented the Sullivan Machinery Co. in Alaska, is now district manager for that company at Salt Lake, Utah.

The Stimpson Equipment Co., Salt Lake, has established a testing plant at 18 Fourth South street, that city, to make demonstrations of efficiency and results with Janney flotation machines. The plant is in charge of Frank A. Bird, a metallurgist who has had much experience in flotation work.

The Nordberg Mfg. Co., of Milwaukee, Wis., announce the appointment of H. W. Dow as sales manager. He succeeds F. W. O'Neil, who has resigned to occupy an important executive position with the Ingersoll-Rand Co., New York. Mr. Dow has been associated with the company in the engineering and sales departments for 12 years.

The McFarlane-Eggers Machinery Co. has been formed to take over and operate the business of the Peter McFarlane & Sons Iron Works of Denver. Henry Eggers is president of the new company and F. McFarlane, secretary and treas-

urer. Mr. Eggers is well known throughout the west through his connection with the Mine and Smelter Supply Co. of Denver. The company will manufacture mining and milling machinery, which will include the development of a number of specialties.

NEW PUBLICATIONS.

Preliminary Report on the Tolovana District, Alaska. By Alfred H. Brooks. Washington, D. C., U. S. Geological Survey. Bulletin 642-G; pp. 9; illustrated.

The district is located in the east central part of Alaska, west of Fairbanks. Though gold was discovered in the district in 1892 it was not until the middle of 1914 that placer discoveries came to make the present importance of the district. Gold placer operations, geology, topography and commercial conditions are briefly reviewed.

Geology and Oil Prospects of Cuyama Valley, California.

By Walter A. English. Washington, D. C., U. S. Geological Survey. Bulletin 621-M; pp. 25; illustrated.

This area is situated between the Santa Maria and Sunset and Midway fields, which have been large producers for many years. The formation of these producing fields underlies the Cuyama field. This with many other designations of oil has attracted the attention of oil men to the field for many years, but development has been retarded by remoteness from transportation. Little drilling has been done and the description of the geology of the area as here given is based almost entirely on surface indications and phenomena.

Natural Gas Resources of Parts of North Texas. By Eugene W. Shaw, George C. Matson and C. H. Wegemann. Washington, D. C., U. S. Geological Survey. Bulletin 629; pp. 129; illustrated.

Because of the fact that Dallas and Fort Worth are so dependent on the gas and oil from the surrounding country, it was at their request that the investigation included in this bulletin was made. Besides the detailed study of the two well-known fields in the district, as regarded geologic structure, possibilities and resources, fields were investigated where there were surface showings of oil and gas or where the structure of the formation indicated that there would possibly be oil or gas.

Geology and Coal Resources of Castle Valley in Carbon, Emery and Sevier Counties, Utah. By Charles T. Lupton. Washington, D. C., U. S. Geological Survey. Bulletin 628; pp. 88; illustrated.

The causes which led to the investigation from which this bulletin is written were first to obtain more specific data regarding the coal field of which little was known and second to prove the area to be mineral land and thus open it for location to which the greater part of it is now closed. The area is located south by a few degrees east of Salt Lake City. Known coal mines and seams are given separate descriptions and in other respects the book is confined to a general geographic description of the country and more detailed description of the geologic formation.

Mines and Mineral Resources of California by Counties. By W. B. Tucker, Walter C. Bradley, G. Chester Brown, F. L. Lowell and R. P. McLaughlin. San Francisco, Cal., State Mining Bureau. State Mineralogist's Report, 1913 to 1914; 5 volumes; illustrated.

The report treats each county separately and the information for each county is of a similar nature aside from the fact that the minerals found in the county and considered, are taken up with different degrees of completeness according to their importance. The text is all of an economic geological nature. The localities in which the different belts of minerals are found are given; in the more important instances the nature of the mineral and its occurrence is described and in considering the most important minerals descriptions of some of the properties are given.

Late News From the World's Mining Camps

Editorial and Special Correspondence.

ALASKA.

Valdez.

The mill at the Granite Gold mine has resumed operations, following a several weeks' shut-down, during which extensive development of the property was done. Col. B. F. Millard, president of the company, states high-grade ore has been encountered in the extension of the hoist level, while a good grade also has been opened in the 210 level and the 350 level. In the upper tunnel a 2-ft. vein, carrying more than \$200 a ton, has been crosscut, and another vein, joining the main vein at this point, about the same width and carrying equally good values, has been encountered. On the 210 level the vein has been cut at about 500 ft. vertical depth, a number of assays of the deposit showing average values of \$160 the ton. An 80-ft. crosscut from the 350 level has picked up the main vein, which at this depth is about 2 ft. wide and carries the same high values as in the upper workings, and in the Granite end of the group development has revealed a 3-ft. vein of good milling ore. Millard is confident that there is enough ore in sight now to assure operating the mill for an indefinite period, and that further development will open additional reserves. In fact, he seems to think that the physical condition of the property is better than ever before, and that a steady improvement in the extent and value of the ore bodies may be anticipated.

ARIZONA.

Prescott.

Reduction of ores from the First Home mine in the Big Bug district will start next week. The mill on the Oriental property was recently purchased by the First Home management for that purpose, and has been repaired and modernized—including an oil-flotation unit. The First Home was taken over recently by local and Los Angeles mining people. Since then the old workings have been cleaned out, the shaft re-timbered to a depth of 300 ft., and the ore bodies developed to warrant the mining and milling of ore. The ore is silver and lead, and prevail generally throughout the mine workings. Ed Block, of Prescott, owner of the property for more than a decade, retains an interest with the present operators. W. H. Worthington is in charge of the mine.

The recent closing of a deal for the Monica mine in the Kirkland country has quickened mining activity and stimulated the demand for mining properties there. Among the more recent transfers is the Stein copper group to the Lucky Strike Co. The McMahon mine is again in the productive class and will send out 2 carloads of ore the latter part of this month. The old Vesuvius mine is once more being operated and is responding satisfactorily to the development plan in force. In fact, the entire mining country adjacent to Kirkland is, like the remainder of Yavapai county, experiencing an hitherto unprecedented mining revival.

The Harqua Hala Bonanza mine started September by shipping a bar of gold bullion worth \$6500 to the Bank of Arizona, of Prescott. The bullion represents a run on about 900 tons of oxidized ore mined in the upper levels in the vicinity of the old "Castle Garden" stope, from which approximately \$2,000,000 worth of gold-bearing ore was extracted in former years. The property was taken by the Yuma-Warrior Mining Co. about 3 years ago, and since that time has been developed more with a view to opening and blocking out ore in the sulphide areas than to maintaining a regular production from the oxidized areas. A tonnage suf-

ficient to meet a portion of the expense attaching to exploration work in the lower levels is, however, mined and billed with monthly regularity. The property is located about 8 miles from Salome, a railway station on the Santa Fe, Prescott & Phoenix railroad, and is being operated under the joint management of J. B. Martin and H. William Stevens. A body of sulphide ore of promising extent and copper values has been opened on the 7th and 8th levels. Prescott and Chicago mining and business men dominate the affairs of the Yuma-Warrior Mining Co. and have to date supplied the funds necessary for exploration work in the sulphide ore zone—that is, funds other than those derived from the sale of the Harqua Hala Bonanza bullion.

Oatman.

Development of a body of high-grade ore in the Crown City group, control of which is owned by the Tom Reed Co., extends the proven district of Oatman 1½ miles to the northwest, from its former limit at the United Eastern. For several months the company has known of the existence of \$10 to \$20 ore there at 60 ft., but now at 75 ft. it has values ranging from \$80 to several hundred dollars.

In the Bald Eagle shaft, near the south end of its holdings, the Tom Reed has made another strike of the greatest importance. The shaft is a few hundred yards northwest of the Aztec shaft, where a recent strike brought life back to Oatman after a quiet summer. Its situation proves that the Big Jim and main Tom Reed veins are distinct. Values are from \$20 to \$50, similar to those of the Aztec.

In the Martin tunnel the Times mine has opened a breast of 8 ft. of solid ore assaying \$12.81.

A high-grade vein drifted upon several months ago in the Pioneer mine has been reopened by Supt. George F. Moser upon his again having charge of the property. It carries values of \$100 a ton and in places is 10 ins. wide. It appears in a south drift from an east crosscut on the 400 level, in the direction of the Arizona-Tom Reed, Paramount, Gold Dust, Boundary, Cone and Lexington-Arizona, the Golconda being on the west of the Pioneer group.

The Orion Co. has finished sampling the Oversight shaft and other workings, obtaining values from \$12 to \$20.

The Boundary Cone continues to drift in its two shoots of milling ore at the 550 and 750 levels. Values show no signs of diminishing.

The Nellie is trenching at the spot where it made its recent surface strike and pannings, and assays indicate values from \$2 to \$19 a ton. At the same time it is crosscutting the ledge at a depth of 350 ft. Values as the foot wall is approached are improving and as they stand will pay hereafter to mill.

Chloride.

The Keystone mine has opened up on the 300 level, 8 ft. of ore assaying 226 ozs. silver and 14.10 ozs. gold. The Keystone and Silver Keystone are sinking a joint three-compartment shaft midway between the properties. It will be utilized by both companies when hoisting ore for the new mill which is now being constructed.

The Black Jack has let a contract for a new road from the mouth of Alum Wash to the property. When completed the ore will be hauled down on auto trucks. At the present time a large number of burros are being used in packing down the first shipment, which will be in the neighborhood of 250 tons.

The Copper Age is to build a mill immediately. A reservoir is now being built, preliminary to the mill work.

The old Silver Hill mine is again in operation after being closed down for a number of years. The 600-ft. tunnel is being cleaned out so that the ledge can be sampled. It is said that bad management is chiefly responsible for the

failures made in operating this property in the past. It also has historic value, being the oldest property in the district. One of the old shafts was the death trap of three of the early-day miners, who were stoned to death by Indians.

Julius Kruschmitt last week sampled the Golden Hammer, the Brunswick and the Holmes properties at Hackberry. He took his samples to El Paso for assay.

The Tennessee Extension has a force of men employed and a contract has been let for an extension of the tunnel.

The Towne mine has ordered a new compressor, hoist and head frame. When these are installed a new shaft will be commenced, the old shaft being in such bad condition that it cannot be used. This is one of the old properties of Chloride. It was recently unwatered and sampled, with good results.

The new power line will be in operation in Chloride in about 3 weeks. Much electrical machinery will be installed.

Eight hundred and seventy-three cars of ore were shipped from Chloride during 9 months ending June 30, according to the Santa Fe records.

Miami.

Development is to be started at the Miami Mother Lode Co.'s property. The property is traversed by several well-defined ledges on which there has been some development, and ore has been encountered in all of the shallow openings. Preparatory to sinking the Cracker Jim shaft to 500 ft. and drifting on the vein at several levels, the equipment is being overhauled and added to. A compressor, purchased in San Francisco, is expected to arrive, and a storage tank for fuel oil is being constructed. As soon as the compressor is installed, three shifts will be put on in the shaft. Several months ago exploratory work at depth on the vein disclosed high-grade sulphide. This is to be drifted on and the vein crosscut.

Globe.

The Miami Con. has recently been formed and capitalized at \$2,500,000. The company owns 1200 acres and is the consolidation of 19 different groups. The ground owned by the company has been worked for many years and hundreds of tons were shipped before the depression in the price of copper. At points where the ground has been opened the formation is shown to be identical with that at the Live Oak and Keystone mines of the Inspiration Con., which lies directly northwest of Miami Con. There is every indication that the body runs southwest from the Keystone and Live Oak, which the new company adjoins, directly through Miami Con. Further indication of this is seen in the fact that 400-ft. drill holes show the same formation at the same levels that have been encountered on the Live Oak and Keystone. Miami Con. is confident that it will encounter the same body of sulphide that was found by the Inspiration at 700 ft. in the Live Oak property.

CALIFORNIA.

Harrison Gulch.

The Victor Power & Development Co. has ordered a large Diesel engine for the power plant of the Midas mine, and expects to have it in position by Nov. 15. It will consume California crude oil and will displace the wood-burning engine now at the mine. President J. H. Sharpe states a yearly saving of \$15,000 in fuel bills will be effected. Unwatering of the Midas shaft to the 1300 point is to be carried on immediately, and from the bottom levels drifts will be thrown out to seek extensions of the Midas, Gold Hill and other veins.

Crescent City.

Frank Edwards has given a bond and option on his French Hill copper property to a group of California capitalists, according to reports. The mine contains a good tonnage of excellent ore, with the deposits showing a persistent character.

Callahan.

James McKeeney, managing owner of the McKeen mine, has decided to add flotation equipment to the 50-ton mill in the early spring. A large tonnage of good-grade ore has

been blocked out and the mill is effecting a good gold recovery, but the sulphides are causing some trouble. Tests with flotation indicate the sulphides will yield readily to the process. A new tunnel is being driven to open the ledge at further depth.

Goldstone.

Ore assaying \$100 to \$150 in gold per ton was encountered last week on the Gold Ring claim of the United Goldstone group. The strike was made by George Branch and associates and work is proceeding to determine its extent. Lessees are actively prospecting adjoining territory.

The Pacific Mines Corporation is developing good ore on the 300 level of the Bagdad-Chase mine, southeast of Goldstone; 100 tons are shipped daily to the United Verde smelter, at Clarksdale, Ariz., and the management expects to be sending out 150 to 200 tons per day in the near future. The product is reported to net around \$4 per ton.

Sinking of the main shaft of the Goldstone Mining Co. started last week. Ore is being followed and the shaft will be sent to the 700-ft. point. Extensive lateral work is planned and the company expects to start a heavy output early in the spring.

Kennett.

The Friday-Lowden tunnel is in 3400 ft. and is expected to intersect the main Mammoth ore channel within 700 ft. at a point fully 600 ft. below the main workings. The Sutro tunnel is in 700 ft. and will be extended a total length of 3000 ft. Both tunnels are exploring wide areas of virgin and highly-promising territory. Grading for the zinc plant is proceeding rapidly and structural work will soon begin.

Jackson.

The strike situation along the Amador section of the Mother Lode is fairly quiet, but the past week has witnessed several scenes of violence. Attempts to resume at the South Eureka were defeated by 400 armed strikers, and owners of other properties have made no effort to reopen their mines. Several operators state they will resume as soon as a sufficient number of men manifest a disposition to return to work.

John P. McLaughlin, State Labor Commissioner, has reported the situation as serious, and expresses his belief that violence can be averted only by a speedy settlement. The Kennedy Co. is installing two new boilers in the power house and completing the impounding dam. The Argonaut, Bunker Hill and Central Eureka Co. are repairing underground workings and surface plants, preparatory to resumption of activity on brief notice.

Pine Grove.

The Pine Grove Mining Co. has placed its mill in operation and expects to keep the stamps dropping steadily. Good ore is exposed in the upper workings, and work is proceeding to open the ledges at further depth. This is a new producer and has yielded some very rich ore.

In the Reward mine a 28-ft. ore body has been uncovered by R. Robinson. Of this 8 ft. carries ore of excellent grade. Preparations are being made for a steady output.

Rich ore has been opened in the Kerkoff mine, near Defender, and the operators are expectant of opening a good tonnage. The shoot shows some specimen ore, and the entire face carries quartz of milling grade. A promising gold deposit was opened recently on the old Stirnaman property.

Forbestown.

A small flotation plant has been erected at the Southern Cross and experiments are being made on ores of various grades. A large tonnage of good ore is blocked out and preliminary tests indicate flotation can be successfully applied. Fully \$50,000 has been expended in developing the property.

It is reported a deal is pending for sale of the Forbestown Con. group. This is a consolidation of several of the largest mines in the field, including the noted Gold Bank. Satisfactory flotation tests have been made on Gold Bank ores and a plant will probably be installed next summer.

Local people have taken over a group of 12 claims, lying northwest of the Gold Bank, and are planning to drive a long tunnel from the south fork of Feather river. The Beik mine has been purchased by Hall and associates of Los

Angeles, who are pushing extensive work. The United States Exploration Co., of New York, is unwatering the Carlisle property, and otherwise preparing for extensive work. The Salano Wonder is active, and engineers are examining the Denver.

Placerville.

The Badger Hill Mining Co. has been formed to operate the Badger Hill mine in the Camino district. It is composed of John L. Woods, Charles F. Bryant and Otto G. Koch. The mine has yielded much rich ore and is said to contain a good tonnage of profitable material. It is owned by County Assessor George Rieber.

The south drift from the 500 level of the Pyramid has broken into a vein assaying \$50. The shaft is being sunk to a depth of 700 ft. and drifts will be run to open the new vein at further depth; 24 men are employed.

Jamestown.

Extensive work continues to be carried on in the lower levels of the famous Harvard, for years one of the premier gold producers of Tuolumne county. The 60-stamp mill is running at top capacity and the quartz continues to carry profitable values. Much new ground has been added lately to the productive belt.

The Boitano mine at Groveland has been taken under bond by J. L. Whitney, manager of the Atlas property in the Tuttle town district. Extensive developments will be started within a few weeks. The Boitano has produced much good ore and considerable ore remains in the workings.

Oroville.

The United States Exploration Co. is shipping supplies to its Robinson mine at Granite Basin, northeast of Oroville, and preparing to continue operations throughout the winter months, despite deep snow. The shaft will be deepened to 400 ft., and if ore conditions continue satisfactory, a hydro-electric plant and 100-ton flotation mill will be installed next summer. The company is controlled by New York capitalists. E. N. Miller is superintendent.

Poker Flat.

A new hoist has been installed in the Carey winze of the Herkiner gravel mine, and production of rich material is going on day and night; 25 men are at work and a large yardage of gravel is washed daily. With the new hoist the management expects to take out 100 to 150 cars of gravel per day. Careful prospecting indicates each car will average close to \$11 in gold. Four drifts have been extended from the Carey winze.

COLORADO.

Good Springs.

The Bullion Co. as yet has not opened its ground extensively, but shipments of concentrates and crude zinc ore are being made. In regard to a recent shipment, Joseph J. Daynes, Jr., president, says that the shipment comprised 18 tons. Assays were 14.6 ozs. silver and 61.5% lead. The settlement represents \$74.68 net per ton and the total approximates \$1200. Good results from development is being obtained. The ore found at the greatest depth is richer than that on the upper levels. There is some first-class ore mixed through the mill product, but at the greatest depth the ore is all of a direct shipping grade. The development to new depths is being hurried along. A lead ore was encountered in the crosscut from the 145 level. This crosscut is developing the Daynes vein and there is a good portion of the ore exposed that is of a direct shipping grade. It is expected that within the next 25 ft. the deposit will prove to be a large one and the ore should be of a shipping grade.

Silverton.

B. B. Allen and Celeste Fattor have secured a lease on the Tom Turner property. This property was worked many years. The lessees are making arrangements for immediate work and have been installing necessary machinery, etc. A few men are now employed.

The North Star mill has been started, treating ore from the North Star mine. The mill has been overhauled. The

mine has undergone considerable development in the past 4 months. The work was carefully planned and before the starting of the mill the mine was given the necessary attention.

Clay Johnson has the contract for sinking the shaft at the Dora mine. During the first part of last week he started his men. Three shifts are employed and he expects to complete his task in a short time.

A strike is reported to have been made in the Mayflower, which is now being worked under bond and lease by Slattery, Mears and associates. The value of the body opened is given at \$25,000. The Mayflower is owned by G. H. Malchus of this city.

Georgetown.

A strike has been made on the Hanson-Walthers lease in the Capitol mine. No. 15 raise and a mill run of 4 tons shows 200 ozs. gold per ton. The streak is looking good and the lessees intend to take out at least 12 tons before making another shipment. With this they will ship the tailings they now have, either to the mill at Victor, where the Cresson ore is treated, or direct to the smelter. The other lessees in the Capital are raising and crosscutting for what is now believed to be the gold zone on the hanging wall above the lateral barren plane in the big, continuous copper and lead ore shoot of the Aetna lode. No. 15 raise was the first to go above this barren plane, and from present indications there is no reason that the gold zone should not extend the full length of the mine, as has the copper and lead ore.

Leadville.

The work of draining the ground of the Down Town Mines Co. has been completed and permanent pumping equipment has been placed. Work is now being directed to opening the ore bodies. The lessees who have been operating at the Wolcott and Hibsche shafts in the Down Town section have experienced some difficulty. The first undertaking to operate through the Wolcott resulted in failure because of the water, which prevented the lessees from getting into the old workings, drainage being blocked in some way that could not be remedied without the installation of pumping machinery in the shaft. The expense of such a plant was considered too great. It was decided to move the surface plant to the Hibsche shaft, which was known to be drained. Following the moving of equipment, everything progressed favorably until work had been continued below the old water level in the shaft. Here a large cave in the shaft barred further progress and considerable time has been spent removing the cave and retimbering the shaft. This work is now nearing completion and development in the territory will be under way during this month.

In the past considerable exploratory work has been done by the Fidelity Gold Mining Co. The ore now uncovered appears in the lower tunnel, which cut the vein after driving 1200 ft. Here 4 ft. of smelting ore averaging \$200 has been opened. The ore is iron sulphide carrying 10 ozs. gold and showing high values in silver and copper. It is stated that 200 sacks of the ore have been extracted and will be shipped as soon as trains can be secured to move the ore. Previous work on the Fidelity uncovered a vein of low-grade ore assaying around \$10 to the ton and reported free milling. This shoot, which is stated to be 25 ft. wide and has been traced through the property for 100 ft. Plans for the erection of a mill are now being completed and construction work will be started in the spring. The site of the mill will probably be in Four-Mile Park, near the foot of Bull hill. The present development will be continued till December, when work will be suspended until spring. Should the discovery prove as large and rich as reported, steps will be taken early next year to equip the property for extensive development.

Telluride.

King & Farrell are operating the Gertrude group with a fair sized force. They have put in air drills, are drifting on the Modena vein and will work all winter.

At the Black Bear mine they have a shaft 450 ft. deep and have taken out enough ore to keep 20 stamps at the Smuggler mill going full capacity. The company desires to increase the output, and have commenced widening the shaft

and will install an electric skip. This will double their hoisting capacity. While the shaft is being enlarged a part of the miners will be laid off.

IDAHO.

Wallace.

Although plans for the plant have been prepared, the Consolidated Interstate-Callahan Mining Co. will not build its proposed new mill at Enaville for several months. In fact, no definite time for beginning construction has been decided upon, according to President John A. Percival of New York, who spent several days at the properties. Even when the new concentrator is built the present plant will be maintained in service until the ore reserves on the Nine-Mile side of the mountain are exhausted. "We have at least 4 years' supply of ore in the workings tributary to the present plant, and there would be no economy in diverting this to a mill at Enaville, as the product would have to be sent down into the Amazon-Manhattan workings, and thence by aerial tram to the new railway now being built up Beaver Creek," said Percival. "Eventually, however, I feel sure that the proposed mill will be built, but how long before we will begin construction I cannot say. Production is being maintained at the maximum, and the output in September was 6600 tons of lead-silver-zinc concentrates, as compared with 7200 tons in August, but we do not know what the net earnings for the month were, as settlements have not been received. August was the banner month in the history of our company, so far as production is concerned, but we soon will have it increased, as we are installing a new flotation recovery system to work over the tailings that have been impounded near the mill. For the first few weeks after the plant began operating these tailings got away from us, but since then they have been conserved and there is a several years' supply for the retreatment department, which will produce about 800 tons of high-grade concentrates monthly. The additional recovery system will cost about \$50,000, but this amount will be repaid soon after it is in service, probably about Jan. 1. The company will pay the regular quarterly dividend of \$1.50 a share, or \$697,485, on the specified date of disbursement, but I am not inclined to believe that any extra payments will be made this year, as we are building up a surplus fund commensurate with the magnitude of our operations, and excess earnings are being diverted to this account. Excellent progress is being made constructing the new O. W. R. & N. branch line up Beaver creek. Work already is under way with a large crew, and grading is well advanced. Track laying will begin soon, and I was told that about a mile of rails would be laid by Nov. 1."

Hailey.

The \$40,000-option on the Smoky Bullion group of gold-silver-lead claims, 35 miles west of Hailey, held by the United Mines Co., a Spokane corporation, is to be exercised soon, according to E. A. Worswick of Lovelock, Nev., owner of the properties. "The holdings comprise three patented and three unpatented claims and a patented mill-site," said Mr. Worswick. "Better than \$75,000 have been expended in development and a considerable tonnage of ore has been exposed. One vein has been opened by surface cuts for 2000 ft., showing the ledge to be one of 4 ft. wide and carrying average values of about \$40. Another shoot has a width of 4 to 30 ft., in which there are three streaks of solid ore 6 to 8 ins. wide, and at one point there is a streak of solid lead ore 16 ins. wide that is in shape for shipment at once. The higher grade material assays 65% lead, 45 ozs. in silver and a few dollars in gold to the ton. The new company, of which Thomas S. Griffith is president, Charles Uhden treasurer, and George P. Larsen, secretary, contemplates beginning operations in about 30 days. There is more activity in the Wood river district than for many years, the entrance into the field of eastern capital having given mining a much-needed impetus. The Federal Mining & Smelting Co. already has invaded the field, having taken over the North Star-Triumph group, which it will have on a producing basis as soon as the new 200-ton mill now being constructed is operating; a New York syndicate has acquired another dormant property

there for \$100,000, and the Stewart Mining Co. is investigating several claims with a view to purchasing them."

The Nay Aug Mines Co. mine, in the Wood river district of southern Idaho, has been purchased by Raymond Guyer, of Spokane, general manager of the Rex Con. Mining Co. It is said that an eastern syndicate is identified with the corporation that is being organized to take over the property, which has been worked intermittently for the last 30 years, and is credited with production estimated at approximately \$750,000, gross. The property probably will be transferred to the Idaho Exploration Co., capitalized for \$100,000, which is being formed to engage in development of Wood river holdings. If development work warrants the company will install a modern mill of sufficient capacity to treat the output. These improvements will represent an expenditure of about \$75,000. There are two shoots of ore, running about 40 to 49% zinc, remaining untouched in the 500 and 700 levels, the former operators having removed only the lead-zinc product, and it is estimated that there are not less than 40,000 tons available for immediate extraction in these bodies. It is intended to sink 300 ft. from a point near the face of the No. 7 tunnel, now in 2200 ft. Adjoining ground has been acquired by the Silver-Lead Mining Co. with which Darwin Utter, former surveyor general of Idaho; M. Miller of Kansas City, and Raymond Guyer have the chief interests. The ground is virgin, but engineers say it is as promising as the Nay Aug and has a continuation of its vein. A tunnel has been driven 450 ft. and lacks 150 ft. of the body, which is 1 to 6 ft. wide, contains lead and silver, and in these and other particulars is characteristic of the Wood river country. These properties are 12 miles northeast of Hailey.

Burke.

The capitalization of the Laclede Mining Co., which owns and is developing the Laclede mine, near the Hercules holdings, was increased from 1,000,000 to 1,500,000 shares at \$1 each, at a recent meeting of the stockholders in Wallace. The company intends to dispose of stock to defray expenses of equipping and further developing the property. Present development consists of 1600 ft. of tunnels, 1200 ft. of drifts and 300 ft. of shafts, opening four different levels, but in none has commercial ore been encountered. Operations have been suspended until February or March, when more extensive development plans will be inaugurated.

Development of the West Hecla group of lead-silver claims is now being confined to drifting on what is believed to be the extension of the main vein of the Hecla mine, adjoining, and two shifts of miners are employed, according to J. V. Pohlman, of Spokane, secretary-treasurer-manager of the West Hecla Co. The drift starts from a point 1800 ft. in from the portal of the crosscut, and the vein now has been followed for more than 100 ft., promising mineralization being shown the entire distance. The vein, which has the same dip and strike of the Hecla vein, is soft and easily worked, and the general formation is almost identical with that exposed in the Hecla workings. "There are 2000 ft. of this vein in West Hecla ground, which is near the Hecla Co.'s principal holdings, only the Galena fraction intervening," said Pohlman. "The Hecla vein has been opened to within 290 ft. of the east end line of the Ophir claim of the West Hecla group, and the indications are that this ore body extends into our territory. Our property is adjoined on the west by the Standard-Mammoth group, and to date we have run 2200 ft. of crosscuts and drifts, opening the mine to 700 ft. vertical depth. Our property comprises three patented claims, the Bamboo Chief, Ophir and Ruby, lying in the center of three of the heaviest producers of the Burke district, the Hecla, Standard-Mammoth and Tiger-Poorman, both of the latter being owned by the Federal. The Sherman Development Co., operating the Union and Hidden Treasure claims, lying immediately north, has opened a very important ore showing, and the indications are that this corporation will become one of the big producers of the district. This deposit bears no relation to the West Hecla bodies, but it demonstrates the extensive mineralization of the region. Between 700 and 800 ft. additional depth can be obtained by running a lower tunnel, enabling us to begin production very quickly in the event that we encounter commercial ore. The West Hecla company is officered as follows: Morton Webster, Wallace, is president; R. H. Bailey, Spokane, vice-

president, and J. V. Bohlman, secretary-treasurer. These, with Dr. Thomas A. Russell and Arthur A. Boothe, of Spokane, complete the directorate."

LAKE SUPERIOR.

COPPER.

Houghton.

Hancock produced in September 341,195 lbs. of copper from 22,588 tons of rock, making the yield 15.5 lbs. a ton. This is an increase of thirty-four one-hundredths of a pound in the yield. Both No. 2 shaft and Quincy No. 7 are giving a better yield, the latter running about 19 lbs. At the Centennial-Allouez the mine is sending about all the rock that can be handled there for the present—about 650 tons, but can send a vast amount more than it is sending to the Quincy mill, which is milling the rock hoisted through its own shaft, where it will bring up between 8000 to 9000 tons this month, as compared with about 7000 for September. More stopes are being opened as men are coming in more freely.

Wyandot is now running into excellent grades of the metal on the 10th level, where it has begun again to extend its drifts which had only covered a distance of about 25 ft. in each direction. The two stopes that have been opened for 3 or 4 months back, and which are getting pretty well up to the 8th level, are also in good ground. From both of these sources a stockpile is being accumulated that will be large enough to be milled at the Winona mill sometime before the holidays. The indications are that the returns in mineral will equal if not exceed those of the first mill test which were 28 lbs.

Victoria is gradually getting into condition so that the tonnage can be greatly increased; the new hoist is working very steadily; the track on the new skipway is laid except between the two lowest levels; and the waste rock has been all hoisted out of the way. The output for last month was 165 tons; and the production of refined copper will be increased about 25% this month, principally because more ground was available and a better selection could be made, though there was some increase in the tonnage. The 23d level east and the bottom level, the 26th, are exposing some high-grade rock. The former has a mass that has been uncovered for 8 ft. without any sign of its end being in sight. Sinking will be started again shortly. Geo. Hooper is superintendent.

Keweenaw began stamping the first of its rock from the Ashbed lode the 14th, working about 6 hours. For a few days the old Phoenix mill where the rock is being treated will run only on the day shift until the machinery is running smoothly. The old Ball stamp has been put on a firm base and is operating very efficiently. This beginning is both a mill test and the commencement of the mine's production which will be carried on indefinitely.

New Baltic has its shaft pit down about 25 ft. without any indication of the ledge, which will be run into at the depth of from 40 to 50 ft. The timber is about all ready to be set up as soon as the ledge is reached. President R. H. Shields is very anxious to get to sinking as soon as possible to make up for the unavoidable delay in scouring the shaft site.

New Arcadian is now cutting out its loading station at the 1500 level as it sinks the shaft, and will soon begin to cut out its crosscuts to the New Arcadian lode, and to the lode encountered on every level back of the shaft about 15 ft., and also for quite a distance beginning with the 1400 level in the shaft with paying grades of copper. It will drift on the latter lode enough to get an estimate of its average. Some good copper is being met with in the two drifts at No. 2 shaft which is on the lode supposed to be the Old Arcadian on the 150 level.

Isle Royale's output has declined slightly to about 2825 tons daily from about 3000, which has been maintained for 3 months or so on account of the want of men.

Wakulla, which comprises 480 acres located about 5 miles west of the Norwich or Copper Crown, was recently examined by Henry Hillegas of Houghton for the owner, W. J. Lan-

don, a banker of Winona, Minn. Hillegas had the assistance of a geologist of this district and found some promising lodes; he also made estimates as to the cost of reopening, etc., and embodied findings in a report which the Mr. Landon now has under consideration. It is rather likely that the latter may decide to explore the property.

Michigan, since finding the mass copper on the Ogimah lode, has been in a very good quality of stamp rock, and is now crosscutting to the fissure vein which parallels the amygdaloid, and which was very good when it was passed through by the main crosscut. The width of the mineralization the second time it was passed through was about the same as when first opened—6 to 7 ft. The main crosscut is now 180 ft. from the Ogimah, and is not meeting with anything of importance. Nearly 2 tons of mass was taken out of the Butler lode last week. The west drift has met with considerable copper, but at the present time is passing through a fault of trap. The east will be soon connected by a stope with the 5th level, and for the past few days has disclosed only a little copper, and that was stamp grades.

Flint Steel under the direction of Supt. Samuel Brady of the Michigan, has men cleaning up the surface and examining the three old shafts on the Butler formation, which they report to be very promising. It is now being decided from the data obtained just where to begin, and this question will soon be settled and the work of pumping out the water will be started at once.

Calumet & Hecla's new smelter, which will have a capacity of 2,000,000 lbs. a month, located at Dollar Bay, will be in commission in a few days. This is an additional smelter which is required by the increasing amount of mineral and mass that is coming from the mines whose smelting is done here—the Osceola, Tamarack, Ahmeek, Isle Royale and Centennial. The capacity of the smelter, outside of the new smelter, is about 5,000,000 lbs. monthly. The plant is exceedingly well situated, as it is on Portage Lake, which is a part of the waterway crossing the Keweenaw peninsula used by all of the shipping coming to the Copper Country, and on which are Hancock and Houghton. It is about 5 miles south of the Calumet & Hecla smelter at Hubble.

Houghton Copper is still in the good ground encountered on the 4th level of the Superior lode recently opened by a crosscut from the shaft, a distance of 250 ft. The north drift at the distance of over 130 ft. from the winze on the bottom, the 12th level, for the first time since the drift was started, is in a somewhat lean but short stretch. The West vein is disclosing but little copper, but the stoping on the 6th level is still meeting with good grades.

Cherokee, which is now down about 110 ft., at the depth of about 90 ft. passed through a horse of trap and below it ran into the mineralization again richer than before, which has continued to the bottom.

IRON.

Iron Mountain.

The Peninsular Power Co. will soon supply the Indiana mine with electric power and it is the intention to commence the construction of the transmission line at an early date. The initial installation will supply the crusher and pumping plants. In the spring an electrical haulage will be installed and a number of individual motors for other purposes erected. The company will soon commence the erection of machine and blacksmith shops, and the building will be 60 by 40 ft. Dwelling houses will be erected this fall. Supt. Richards complains of a labor shortage and says he could employ a considerable larger force, if the men were available. The ore is smelted in the furnaces of the Thomas Iron Co., Milwaukee. The pig is shipped to New Orleans and from that port to Italy, at present.

Wakefield.

Considerable activity is being noted on the part of the Gogebic range. The Hanousek pit was not completely stripped before steam shovels were placed to start production. With the closing of the shipping season soon the stripping of overburden will be completed. M. A. Hanna Co. is to start another big pit near its Wakefield mine. Seventy feet of overburden covers the deposit and the waste will be removed by hydraulic. About 600,000 cu. yds. in all will be

stripped. The course of a small creek will have to be changed. The company has made the necessary arrangements with adjoining land owners to carry out this work. At the outset the ore will be taken from the pit to surface on an inclined track, but later it will be milled and pulled to surface through "B" shaft. The new mine will be known as "C" pit.

The Castile will install two 500-gal. electric pumps that have been ordered from Fred M. Prescott, Menominee. These are to care for the additional water that is expected to be encountered in opening up the 19th level. The plat and pump station is being cut on the 19th, the shaft having been completed from the 17th to 19th recently. The pumps will be installed and running by the spring of 1917, when the 19th level will be developed.

The Sunday Lake mine is installing a Greene economizer and equipping their boilers with automatic stokers. They will wash away the ashes with a stream of water running in front of the boilers as at the Castile. They have extended the boiler house 30 ft. west. The mine has shipped about 40,000 tons to lower lake ports, the analysis being 37 to 40% iron.

Ramsay.

At the Eureka 16 new company houses are to be built and bids have been called for. Further it is to soon purchase a first-motion steam hoist for the No. 2 shaft. The shaft is timber and will have to be repaired before hoisting can be done through it. It will be used to mine a pocket of ore found in the western portion of the mine, near the boundary line between this and the Anvil mine, which, however, is not considered an extension of the Anvil ore body. A diamond drill hole from surface to a depth of 1100 ft. with the idea of locating the extension of the Anvil ore body is to be sunk. This hole will be put down 500 ft. east of the Eureka-Anvil line.

MISSOURI-KANSAS.

Joplin, Mo.

For 6 consecutive weeks shipments of zinc ores have been heavy, and in every instance have been greater than the production. Naturally this has resulted in a heavy depletion of ore stocks. From a total of 26,566 tons in stock at that time, there have been shipped sufficient to reduce it to 12,000 tons this week. This, too, is in the face of a slightly increased output. These new conditions place the district in a much better position statistically than it has been for many weeks, and relieves the operators greatly, for there was a period during the spring and summer months when it appeared that every week marked an increased output and a decreased demand for the Joplin product. As a result stocks assumed huge proportions, and at one time exceeded 30,000 tons, the largest figure ever known in the field. Rapidly decreasing ore prices, together with the accumulated stocks, forced the closing of many mines, but with a renewed buying activity there is again a tendency to resume operations in so far as local conditions will permit. The low waters of Spring and White rivers, which are the sources of power for the plants which supply the Joplin district with electric power, have been so low that the maximum power is not available, and many patrons of the plant have been forced to wait till the fall rains raise the rivers, or turn their plants into steam-driven ones. The gas engine plants are also experiencing trouble, in that they cannot get sufficient gas for regular power, and this last week has been one full of difficulties for all those having either electric or gas-engine driven mills. Every winter season sees difficulties for the gas engine plants, but this has been the first year when there was an actual shortage of electric power. Even supplemented with steam turbine plants, the electric power company has been unable to meet their patrons' requirements.

Southwest of Joplin the Adams-Hicks Zinc & Lead Corporation, owning a lease of the Mattes Bros. land, has been opening up a good deposit of ore. This is being mined and milled by the company itself, but in addition to this the company has sublet a portion of its lease to small operators,

who have been prospecting the shallow levels, and they have opened up some remarkably good ore. J. H. Handsford of Joplin is one of the principal owners.

With excellent fall weather prevailing there has been a great deal of prospecting and development work under way all over the district, and at no place has the prospecting been more general than in the Joplin camp. In the old Chitwood camp the Coffeyville Mining Co. has opened up a prospect of merit. It has two drifts now running 10 to 20% zinc blende and in each case the deposit seems to be widening out. The face is 12 ft. high and carries both lead and zinc. The company is now planning on the early erection of a milling plant. John West of Joplin is the local manager.

In the Leadville Hollow camp John T. Phipps and Chas. W. Edwards of Joplin have been doing some prospect drilling that has shown some very good results. One of the last holes put down encountered 11 ft. of ore at the 50 to 61 levels that assayed 20% zinc. Nine drill holes have been put down so far, and only one hole failed to show ore. Some of the deeper holes showed a 28-ft. face of ore. The company has a 16-acre lease immediately in the heart of the old camp, and the work of development will be hastened before the severe winter weather sets in.

In the southeast part of the Joplin camp there is a number of new prospects and much of the old ground known for years as shallow producing territory is being re-prospected, and in many cases with good results. On the Robb land the Old Friends Mining Co. has recently uncovered a deposit of ore at the 80 level which is considered very good. The ore is in soft ground, and with further development the owners expect to keep a 150-ton mill running steadily.

Johnson and Tatum have just struck what appears to be a good zinc prospect on a lease of the Missouri Lead & Zinc Co. land. The ore is found at a shallow level, and is said to run nearly 25% lead and zinc. The owners are this week installing hoisting equipment and will be better able to open up the prospect hereafter. Another prospect on an adjoining lease is the Honey Bee Mining Co. shaft, where at a depth of 150 ft. a good run of ore has been developed by drilling and a shaft is being put down to that level.

After milling tailings for many months the Grandtower Mining Co., west of Joplin, has opened up a good prospect by drilling its lease beneath the old tailings pile, and finds that a considerable portion of its ground has ore at the 65 to 105 levels. Some of the ore ran as high as 10% and was found in a disseminated formation of spar and flint. A shaft will be sunk to open up this new discovery, while company will continue its milling of the old tailings pile. Those interested in the property are J. M. Evans, J. C. Finke, L. R. Parker of Joplin, and L. L. Hutchmaker of Grandtower, Ill.

On the Thompson land southeast of Joplin two leases are being developed, one by the E. & N. Mining Co. and the other by Smith, Moore & Co. Both companies are engaged in sinking shafts upon recently drilled ground where drill holes showed the existence of ore at a depth of 130 to 206 ft. The shafts have been put down to 115 ft., but here the water has been found to be so strong as to seriously interfere with further sinking. A concerted effort is being made to overcome the head of water and heavier pumps will be installed.

Galena, Kan.

Frank B. Wilcox and W. S. Watson of Joplin have just taken over a lease in the heart of the Galena camp with the intention of erecting a mill at once. The property has been known as the Lone Elm mine, and it has been producing well over hand jigs and a custom mill. The ore has milled out as high as 9% zinc, while the concentrates have run up to 63% zinc. The new owners will rename the property the Premium Mining Co. The company has a 10-acre lease of practically virgin ground in the very heart of the old mining camp.

In the Cave Springs camp, near Galena, Mustain Bros. have taken hold of a 40-acre lease and have been successful in bringing it to the production point. The company now has three shafts producing from the 103 level. Besides the Mustain activities there are several lessees. The company expects to put up a concentrating plant for cleaning its own ores and will also handle the ores of its sub-lessees.

MONTANA.

Butte.

There were 48,809 tons of ore treated under the oil flotation process at the plant of the Butte & Superior during September, and 12,694 tons of concentrates were recovered, according to report submitted by the mining company officials to the federal court. Of the amount of ore treated in its oil flotation plant, 48,809.7816 tons; of the amount of concentrates recovered in its oil flotation plant, 12,694.2915 tons; of the analysis and assay returns of heads in its oil flotation plant, 14.8415% zn., .9494% pb., .1534% cu., 2.5475% fe., 1.7308% mn., 66.8589% insol., 6.1882% oz. ag., .0058% oz. au.; of the analysis and assay returns of concentrates recovered in its oil flotation plant, 53.659% zn., 3.167% pb., .509% cu., 3.010% fe., .303% mn., 8.672% insol., 21.720% oz. ag., .0322% oz. au.; of the cost of flotation per ton of concentrates recovered in its oil flotation plant, \$3.1725; of the value per ton of concentrates recovered in its oil flotation plant, \$48.69. The figures set forth under the foregoing six paragraphs are, as noted, approximate estimates, for the reason that at the date of the filing of this statement no exact information has been acquired by the Butte & Superior Mining Co., so that accurate figures can be given. As to the analysis and assay returns of tails from the oil flotation plant, the following figures are accurate and not estimates, 1.0900% zn., .0600% pb., .0800% cu., .8000% fe., 2.0000% mn., 88.4000% insol., .7900% oz. ag., .0020% oz. au.

The north crosscut on the 160 level of the Butte & London apparently is approaching a ledge, one of the series of large fissures cut in the property of the Rainbow Lode Development Co., adjoining the Butte & London. A number of stringers were intersected and for a time it was believed that the vein had been entered, but as the breast was driven ahead it was shown that the fissure had not been reached. The fissures where cut on the 1500 level at the Rainbow are large and strong and show a good state of mineralization, carrying copper, silver and zinc values. One of the largest of the Rainbow fissures is that of the Third Sphinx, a fissure showing an outcrop with a width of about 40 ft., and striking directly for the northern part of the Butte & London.

Great Falls.

The new zinc plant is far more than meeting the most enthusiastic expectations of the company and work is in progress in laying the foundations for a "bag house" which will cost more than \$100,000, the same to be completed about Jan. 1, is the important feature of the news given out by C. F. Kelley, managing director of the Anaconda Copper Mining Co., while here this week. With Mr. Kelley were C. W. Goodale, manager of the company; John Gillie, superintendent of mines; Frederick Laist, chief metallurgical engineer; William Tanner, chief engineer, and one or two other officials of the company. "With but two units of the zinc plant complete, we have already found it is going to be a most gratifying success, from every standpoint," said Mr. Kelley. "There was an output of 60 tons of zinc at the plant in one day, while the theoretical capacity of the two units was but 50 tons, so it will be seen that it exceeds capacity expectations by 20%. The plant is working satisfactorily in every particular."

Mr. Laist talked about the "bag house" which is now being constructed. He said that it would be 50 by 150 ft., ground dimensions, and about 50 ft. in height. In the building there will be 1440 bags, which will be used to get the lead from the fumes that come from the reverberatory furnace. The bags will be arranged with the mouth at the floor and the fumes will pass into them and all except the lead will escape through the bag. "This new building will be erected with our own forces," said Laist. "The work of putting down the foundation is now under way and there is expected to be no trouble in getting the bag house completed by Jan. 1. It will enable us to save the lead that, without the device, is not being saved here."

Concerning the zinc plant, Laist said that there had been an unexpected delay in getting certain of the heavy electric machinery, but that the manufacturing company had prom-

ised to hurry the remaining portions as rapidly as possible and some hope was entertained of having all five units of the plant operating by Jan. 1. "There seems to be pretty good ground for believing we will have four units ready about the first of the year and we might be fortunate enough to have all five. The third unit can be installed as soon as certain machinery now in transit has been received. The first two units have given the fullest satisfaction. As Mr. Kelley has said, the plant is turning out 20% more than the theoretical capacity and is doing it in excellent manner. Because of that fact, we are anxious to get the other units going as soon as possible, but we cannot hurry the manufacturers of the heavy electric machinery and it appears we may even consider ourselves fortunate to have gotten our plant as nearly equipped as we have."

Saltese.

The Tarbox Mining Co. will inaugurate shipments about Jan. 1, according to Manager Richard Daxon. "The shaft now is down nearly to the 600 level, where a station will be cut, pumping equipment installed and a crosscut driven 180 ft. south to intersect the vein," said Daxon. "Drifts then will be run both ways on the ledge, to make accessible for extraction of ore. Power drills and the compressor plant recently installed are working smoothly, and much better progress is being made in sinking the shaft. A sawmill with a daily capacity of 25,000 ft. is being installed to supply lumber and mining timbers. A boarding and bunk house and office buildings are to be built at once."

Superior.

The Intermountain Mining Co., which owns and is operating the Intermountain mine, formerly the Amador, now is netting about \$17,000 monthly, and probably will be able to continue to earn at this rate for some time, as arrangements have been made to secure electric current for power during the winter from the La Casse Bros.' dredging plant, nearby, according to Frank Walker, of Jackson & Walker, Spokane brokers, who returned recently from a visit to the property. "A car of concentrates is being taken every fifth day from the jigs and tables, and an equal amount in the same period from the flotation system," said Mr. Walker. "In addition 1 to 2 cars monthly are being secured from the grizzlies, making the output about 14 cars a month. The product from the jigs and tables runs about 15% copper, and from the flotation system, 18%. This makes the net smelter returns about \$1800 to \$2000 the car, or an average of \$23,000 monthly. Operating expenses are approximately \$6000 monthly, leaving the net earnings \$17,000, or more than twice dividend requirements at the present rate of disbursement, a half cent the share. A new shoot has been found at depth on a side of the gulch opposite that in which the shaft was sunk and two on the No. 2 level. The shoot across the gulch will have 500 ft. of backs at the point of its intersection. A stope on the No. 2 level has a width of 17 to 20 ft. This body has a copper content of 2½%, but streaks having a width of 1 to 2 ft. contain 10 to 11%."

NEVADA.

Goldfield.

The main shaft has penetrated the alaskite-shale zone in the Silver Pick, at a depth of about 1050 ft., and a crosscut is being driven to the west to intersect the shoots of rich ore located by the core drill. It is calculated the ore bodies will be tapped within 500 ft. Arrangements have also been made to develop the shoots indicated in the contact of latite and shale. The work is followed with pronounced interest, as it may open a new ore zone to the west of the Columbia Mountain fault.

The Grandma Con. Co. has doubled its acreage by the acquisition of adjacent ground along the strike of the Grandma-Spearhead ledge. Sinking of the shaft is going ahead rapidly and it is believed the ledge will be intersected within 200 to 250 ft.

Returns from the first carload of ore shipped from the new shoot on the 300 level of the Great Bend were \$83 per ton, according to the management. A winze is to be sunk on the shoot. A raise was recently started and has entered

low-grade material, apparently establishing the upper limits of the rich deposit. Development of the main vein continues.

The shaft of the Spearhead is down 945 ft. and is expected to enter the contact zone at the 990 point. Important lateral work is being pushed from several points.

National.

The new mill erected by the Hatch Mining Co. to treat ore from its lease on the Buckskin National mine is operating satisfactorily. The winze from the 300 level has attained a depth of 25 ft., and a crosscut from this point has penetrated the vein for 3 ft. The ore assays around \$50. Crosscutting continues to determine width of the ledge. A tunnel has been started to cut the vein system 650 ft. below the main workings. It will have an approximate length of 2100 ft. N. P. R. Hatch is manager.

At a point 3000 ft. south of the Hatch workings, the Buckskin National Co. is extending a crosscut tunnel to intersect the Upper vein. It lies about 285 ft. west of the developed ore body, which has been developed to a depth of 400 ft. Forrest Bell is superintendent.

NEW MEXICO.

Mogollon.

Work has been resumed on the Gold Dust Group, in southern part of district. The property has had 1800 ft. of tunnels driven, encountering two ore bodies. These are to be explored further and the main tunnel extended into center of property.

Supt. Cockran of A. Leschen & Sons Co., who are furnishing material for aerial wire rope tramway from Pacific mine to the plant of Socorro Mining & Milling Co., is on the ground superintending installation. Rollers and rim work are being placed on standards and terminals. Practically all the wood work has been completed. The tramway will have a length of 1 mile and a capacity of 10 tons per hour.

The Oaks Co. is getting in supplies and other material preparatory to starting work on its drainage and transportation tunnel on Mineral creek. When completed it will be the largest and longest tunnel in the district, and will encounter the principal ore bodies at depths of 1400 to 1800 ft., and be the means of effecting a great economy in future operations. It is planned to have a large capacity plant at the portal, and eventually centralize all metallurgical operations of the district at this point. The topography of the site is finely adapted to the consummation of this proposition.

Dr. Ransome, of the U. S. Geological Survey, spent the week in camp checking up geological work being done. An appreciable territory will have been covered when the assignment is completed.

OREGON.

Riddle.

The Oregon Nickel Mining Co. recently shipped 2 cars, 100 tons, of chromium ore to the Illinois Steel Co., Chicago. The ore averaged about \$30 per ton and the total value of the shipment was \$3068.95, Chicago.

Kerby.

The Seattle company which purchased the Neill Success mine has also purchased the Geo. W. Finch and George H. Mood mining claims on Fiddler's gulch. The firm is now shipping ore to Seattle to determine the best method for extracting the values.

Canyon City.

The Copper King mine in the upper Grave creek region of Jackson county is being equipped with a concentrating plant of 40 tons capacity.

Prairie City.

At the Cougar mine 7 men are now being employed and a Bryan roller mill is being installed to be propelled by water power. They have also adopted flotation. The ore after it leaves the mill is sent to a tank and oil is placed in the tanks. Agitators in the tank keep the ore moving and the

values are taken off in the bubbles formed with the oil. They also own the Washington and the Klondike group of properties and expect to do some extensive mining here.

The Standard is working a crew of 10 men, drifting on a small vein with the intention of crosscutting a big ledge on Copper ridge.

J. Howell is sinking some prospect holes on the Dixie creek placers. It is rumored that local people are financing the work for the purpose of prospecting the ground for dredging. The work was started some time ago, but had to be discontinued on account of the water. Pumps have now been installed.

The Ophir mine is to be organized into a company by Salt Lake interests. The property has been developed by Jeff Forester. There has been work done on the ground for the last 10 years and a low-grade free gold property has been developed. The ledge is 50 or 60 ft. wide.

The Dixie Meadows is idle and the property is in bad shape. Much of the workings have caved and it will take considerable expense to catch up. It is understood that the company is contemplating some work on the property, it being the belief that with the flotation process the property can be placed on a paying basis.

SOUTH DAKOTA.

Lead.

The Wasp No. 2 has shipped 7200 lbs. of 45% tungsten to the Chemical Products Co., Washington, D. C., at \$11 per unit. The mineral was shipped for making tests in tungsten extraction, which are now under way. Chemical Products has erected a new plant and are conducting experiments for testing their process of extraction. Wasp also shipped about \$6000 worth of ore east.

Deadwood.

A brick has recently been produced from a 10-day cleanup at the Deadwood-Standard mill, now under the supervision of Prof. Dove. At the present time they are running through the mill 55 tons daily, but hope soon to be able to treat 200 tons. There is still considerable work to be done on the mill. The product from the mine is curtailed because they have to do their development work as they go along. The ore that is being taken out is paying for all work and leaving a profit. It is said that the development work which will be necessary before the milling plant can be run at its full capacity will require several weeks to complete. The shoot is 15 to 28 ft. thick and of unknown width. It is said to be the most extensive deposit of ore that has yet been uncovered in any of the flat formations of the district and it is rumored the average is over \$6.

UTAH.

Alta.

The Emma Con. Mine Co. was incorporated last week under Delaware laws by Emma Copper interests. The officials will issue a statement to Emma Copper stockholders during the week. It will have to do with the taking over of the control of the Old Emma mines and the Emma Copper companies. The transfer office of the Emma Con. Mines Co. has been established at 40 Exchange place, New York. The registrar is the Registrar & Transfer Co., 120 Broadway, New York. Stockholders should immediately send their correct address to the Emma Con. Mines Co. at 40 Exchange place, New York, so that the official circular can be mailed to them direct.

Alta Tunnel & Transportation Co. is engaged in driving a tunnel from Silver Creek fork of Big Cottonwood canyon in a southerly course, destined eventually to cut through the mountain to the Alta side, on Little Cottonwood. Driving has been in progress some time, the heading at this date being 2000 ft. from the portal, and for that distance the tunnel is on the company's ground. The purpose of this bore is for mine development, drainage and ore transportation. It cross-

cuts the formation, and thus far has intersected several mineralized fissures; and numerous other similar fissures known to exist will be cut at depths of 500 to 1600 ft. as the tunnel work progresses. A considerable flow of water already has been developed, and by driving about 3000 ft. farther, as contemplated, a large area above the tunnel level will be thoroughly drained. A number of mineralized fissure veins crossing the course of the tunnel have been opened on the surface, and it is figured that this tunnel will make possible their development at great depth, and facilitate ore production on an economical basis. The Clements group, now controlled by this company, has yielded rich ore in workings from the surface, and plans are to open its ore bodies at much greater depth by driving to them from this tunnel. The tunnel with its drainage channel, track on permanent bed, and 10-in. air line, is in excellent condition, and driving is going on rapidly into ground where important disclosures are anticipated. This work is under direction of F. V. Bodfish, manager and mining engineer, Salt Lake.

Eureka.

Tintic Standard Mining Co. has a productive property in Tintic district, 2½ miles east of Eureka. Its location is on the east slope of Tintic range, 500 ft. lower than the collar of Yankee shaft. The shipments of ore during last 4 months were as follows: July, 4 cars; August, 4 cars; September, 8 cars; October, 12 cars. A typical analysis of the ore shows 28% lead, 26 ozs. silver, 15% iron, 60 cts. gold, 0.1% copper, 5% sulphur, 40% silica. The ore occurs in a limestone zone, 400 to 600 ft. in width. This zone is fissured east-west and north-south, and from these fissures the ore makes out into the lime bedding. The development, thus far, is confined to an area 225 ft. east and west, and 50 ft. north and south. This work indicates the existence of a limestone-quartzite contact, the quartzite having the position of a foot wall. It shows an east-west strike of the ore bodies. Development has attained a depth of 1300 ft., in three sections, as follows: A vertical shaft 1000 ft. deep, with a 1200-ft. drift from bottom of shaft on the strike; then at the farther end of the drift is a 200-ft. incline at 49°; this is followed by a drift from the bottom of the incline, at the breast of which is a 400-ft. incline at 30°. This work was exploratory, and resulted in opening excellent bodies of ore. The tonnage and grade of ore exposed justified more permanent improvements and better equipment. A contract has been let to sink a 3-compartment shaft to a depth of 1300 ft., which will strike the main body of the ore; the contract includes timbering, and putting ladderway in one compartment. A Chicago Pneumatic Tool Co. air-compressor, of 840 cu. ft. capacity, electrically driven, has been installed and is in operation. A double-drum electric hoist, ordered from Denver Engineering Works, will soon be in position at the collar of the new shaft. Other new equipment consists of a Sturtevant blower, electric driven, for mine ventilation. The money being expended for new buildings, equipment and new shaft amounts to \$60,000. E. J. Raddatz, president and manager of the company, has had 20 years' experience as superintendent and mine manager in Utah. Salt Lake, Tintic and eastern mining men are interested with him in the company.

Mammoth.

Mammoth mine, Tintic district, is now shipping 725 tons of ore per day, which is an increase over shipments of previous months this year. There are three grades of ore, ranging in value from \$7 to \$80 per ton. The predominant metal is copper, running from 1% to 18%. The main working shaft has a depth of 2360 ft., and the mine at this depth is free from water. The ore being mined comes from the 400, 600, 800, and 1500-ft. levels. The Mammoth has been a producer for 45 years. Dividends were paid this year in April, June and September. The property is controlled by Samuel McIntyre and associates, Earl McIntyre being superintendent.

WASHINGTON.

Molson.

Barney Quinn has given a 2-year lease and bond for \$10,000 on the Denver, Ohio, Valley View and Bluebird claims to George H. Cole, Oscar Johnson, William M. Clark and

David Allen, Butte, Mont., and Portland, Ore. The ledge is 100 ft. wide and assays taken across it at intervals run from \$8 to \$50 in gold and silver.

Laurier.

To date the Laurier Mining Co. has been taking ore from three flat lenses, but these have now changed to a vertical course. Manager Stewart says: "The vertical shoot has a length of 70 ft. at the point of greatest depth attained. It was followed from a point 125 ft. back in the blanket body, where the width is 25 ft. The vertical course was exposed under the stope, from which we removed 55 tons of ore. The ore has the same course as the vein in both the vertical and the blanket body. This encourages belief that the blanket body was a slip and that we are now in a permanent formation. Prospecting has been under way since the suspension of shipments on Sept. 10. We will now increase the force and hope to be on a shipping basis by Nov. 1. Net returns from the shipments were \$18,393.91. This was in payment for 1004 tons contained in 25 cars and at the rate of \$18.32 to the ton after the deduction of freight and treatment charges. The average content was 4.5% copper and 2.4 ozs. silver and the range from 3.4 to 7.6% copper and 2.2 to 6 ozs. silver." In further reporting on conditions, Stewart says: "In the stope from which recent shipments were made the ore has been diverted by a fault or fissure which lies almost vertical and strikes east and west. This fault is well defined and the cleavage of the ore has taken a sudden dip with the fault, instead of continuing on the dip that previous development had shown. In my opinion this fault will control the future of the ore body and the ore will probably be found on both sides of the fissure. The immediate future of the mine depends on the ore following this fault and will be determined by sinking 20 ft. This work will be rushed and a report made on its disclosures in the course of the next month. Shipments will be resumed on Oct. 28, when a lot of 40 to 50 tons will be sent to the smelter. This ore was taken from that part of the vein having a vertical course and is expected to yield 6 to 8% copper."

Republic.

C. S. Cox and J. E. Henwood, Kellogg, Idaho, have been given the contract for sinking and timbering the shaft at the Last Chance mine to the 500 level. The mine is owned by the Lone Pine Surprise Con. Co. of Idaho. It is intended equipping it with compressor, hoist and pump and material necessary for the construction of the shaft. The pay ore now in evidence extends in the Insurgent workings from the 350 level to the 540, at which point it passed on the dip wholly into Last Chance ground. G. C. Taylor is superintendent.

Operations have been suspended at the San Poil mine, taken over several months ago under lease and bond by the West Hill Mining Co., a Spokane corporation. "We could not get our ore up to high enough values to make it profitable," said J. W. Turner of Spokane, president of the West Hill Co. "We had expected it would go \$8, which, with the low freight and treatment rate granted us, would have made us a profit of about \$1 or \$1.25 a ton, for it cost us about \$6.75, all told. Instead of running \$8 it ran just about \$6.75, so we paid expenses, but that is all. It may be possible to do something with this property, for, if a shaft is sunk 300 ft., much better values may be found, as they have been in other Republic mines at about that depth."

WISCONSIN-ILLINOIS.

Platteville.

Reports covering the field for week ending Oct. 21 show delivery to track of 134 cars of zinc concentrates, 5283 tons. Some of the districts were not fully reported. Four cars of lead ore cleared, 125 tons, all going to the Federal Lead Co. Heavy shipments of pyrites came from the Mineral Point Zinc Co., 389 tons; National Separators, 357 tons; Linden Zinc Co., 111 tons. Production last week was 4107 tons. Net smelter product, 3297 tons.

A considerable gain in price of blende was registered, 60% ore and premium grades going on a base of \$63.50, as compared with \$60, reported the week before. The price

ranged downward on second and medium grade ores to \$58 base on ores as low as 50% zinc. A feature of the buying was shown in the increased deliveries consigned to Grasselli Chemical Co., Cleveland, 34 cars in all, 1278 tons, the bulk of this coming in under new contracts recently executed.

Shipments from local producers were light, 5 cars in all. The Vinegar Hill Zinc Co. is operating on a big scale, 450 employes. The Vinegar Hill mines are yielding 800 tons of zinc concentrates, all grades, weekly. Low-grade zinc ore is in demand for treatment at the National Separator Works, Cuba. A 20-ft. winze sunk at the Hodge mine is in a flat of zinc ore. A shortage of labor is reported in many of the mining camps south of Platteville. At this writing the Vinegar Hill Zinc Co. has 12 drilling squads engaged in exploration work, all south of Benton. The introduction of the Whaley type of electric shovel at the Martin mine is regarded as economical under present labor conditions. Some doubt is expressed whether same is true under normal conditions.

Benton.

Returns for week of 21st show delivery to track of 51 cars of zinc ore, 4,178,000 lbs. Fields Mining & Milling Co. and Vinegar Hill Zinc Co. were tied, with 12 cars each. The ores of the former went to Grasselli Chemical Co., the latter to National Separator Works at Cuba. Frontier Mining Co., also to Grasselli, 7 cars, 299 tons; New Jersey Zinc Co., from Penna-Benton mine, 3 cars, 129 tons. This is a greatly reduced output from this mine, while the Fox, another producer for years, has not reported shipments in 2 weeks or more. The Champion reported 8 cars, 318 tons, but this report was not held complete. Sally Mining Co., engaged in building a new boarding house, shipped 2 cars to Cuba, 87 tons. Longhenry Mining Co. reported out a car, the first in many weeks. Shipments from the Benton Roasters went to Eagle-Picher Lead Co., 45 tons, from the Skinner roasters, 2 cars, 80 tons, and 3 cars to American Zinc Co., 115 tons. The Kittoe and Crawhall mines each reported out a car of lead ore.

At the Blackstone mine a shortage of labor is reported. The Martin mine has been supplied with an underground gasoline locomotive. Drilling on the ore body ahead considerable distance has given exceptionally big reward. A new mine and mill will come into active co-operation with other Vinegar Hill zinc producers about Jan. 1 on the Meloy 80. The mill embodies new features, self-dumping cage and underground cars for mechanical shovel operation being installed. The nearest shipping point is Benton, 5 miles distant.

Galena.

Additions and improvements to the main plant of the Inter-State Light & Power Co. is giving employment to 300. Eight contracts have been secured recently covering transmission of power to as many mining corporations. The line is also being extended eastward in Jo Daviess county to supply two new towns, Hanover and Elizabeth. C. C. Whittier of Chicago is providing a surface plant to new lead ranges developed on the Reitz farm. J. H. Billingsley, engaged in prospect work with drill on the Hughlett land, known as Buck Hill, is meeting with exceptionally good results. Pease & Co. are likewise engaged on the Weinen ground adjoining the Black-Jack zinc producer. Henry Priestly has been appointed receiver for the Great Western Mining Co., bankruptcy proceedings being litigated in court. The Little Corporal, a new project with equipment newly installed, has thrown up the sponge. The Fields Mining & Milling Co., operating the Crawhall and Thompson mines at Shullsburg, have recently entered into contract with the Grasselli Chemical Co. of Cleveland for the entire output of these mines. This action eliminates from service the new Galena Refining Co.'s plant at this point, unless the company goes into open market for low-grade concentrates to supply this plant. The city of Galena has served notice on the Galena Refinery Co. to abate the nuisance of gas fumes. It is inferred from this that the plant will not be reinstated for service.

Linden.

The Weigle-Jacobs has struck big zinc deposits in the glass rock, at a depth of 142 ft. Ross Bros. Mining Co. continues running 10 tons of concentrates daily. The force is

working toward the old Glanville mine. The Gilman mine is operating double shift with 60 men and making 160 tons of 40% concentrates weekly and about 25 tons of lead ore. Optimo No. 2 has cut into big ore in the shaft, and two drills are prospecting the range. The Glanville mine is making 15 tons of concentrates daily. Stoner Bros. Mining Co., running on high-grade ore, is recovering 5 tons of 50% jack daily.

Shipments last week were made by the Linden Zinc Co., 2 cars separator ore to Lanyon Zinc Co., 80 tons; Optimo mines Nos. 1 and 2 to local refinery, 7 cars, 255 tons.

Miffin.

Shipments last week showed well, Grunow Mining Co. to Sandoval Zinc Co., 39 tons; Peacock, 2 cars, 84 tons; Lucky Six, 4 cars, 176 tons, and Wicks, a new producer, 1 car, 30 tons, all to Grasselli. B. M. & B. Co. to Benton Roasters, 2 cars, 70 tons; Coker mines to Mineral Point Zinc Co., 2 cars, 70 tons. The Senator, a new producer under Vinegar Hill control, shipped its first car of lead ore. Mineral Point locals delivered small lots, 26 tons in all. The O. P. David mine at Montfort shipped 1 car high-grade wets to LaSalle, 40 tons. At the Lucky Five mine, in the Dodgeville district, an accident resulted seriously for two miners, and several were injured.

Cuba City.

Receipts of raw ore last week at the National plant totaled 18 cars, 787 tons. Shipment of high-grade refinery product was heavy, 10 cars going to Granby Con., 388 tons; 3 cars to Illinois Zinc Co., 113 tons; Linden Zinc Co. to Illinois Zinc Co., 1 car high-grade, 33 tons. Standard Metals Co. of Chicago reported a car out to Wisconsin Zinc Co. for separator treatment, 37 tons. Superintendent George J. Barker, in charge of the National Separator Works, is meeting with good results following the installation of a gas producer plant for firing. No further improvements or extensions are planned.

Dubuque.

The Pike's Peak Mining Co., after a strenuous development program requiring the greater part of a year, is now in operating shape with a new rig complete, and the initial shipment of zinc ore was reported last week—1 car to Grasselli Chemical Co., 53 tons. Incidentally the Grasselli Chemical Co. has been quietly but persistently taking a generous slice of the zinc output of the tri-state field under contract agreements, and now seems to be in a fair way to figure most prominently for 2 or 3 years in the operations of the field.

Shullsburg.

The Oliver Mining Co., operating the Mulcahy mine, after a readjustment of plant and separator, again reports shipment of 2 cars of top grade jack to Edgar Zinc Co. last week, 84 tons. The surface rig is one of the finest in the field. Winskill shipped 4 cars, 138 tons.

WYOMING.

Lander.

Storage tanks are to be constructed by the Wyoming Petroleum Co. and 9 cars of material for this work have been received. An air compressor will be installed for use in constructing the tanks and a complete electric lighting plant was included in the shipment. The company has six producing wells and will increase the number to 20 under its present plans. Two more wells are nearly finished and the rigs will be kept at work until the expected number is completed. At present, owing to a lack of storage, the producing wells are not pumped to capacity. The work of completing the storage and drilling the wells planned on will take several weeks.

Cody.

From the present deposit being worked by the Midwest Sulphur Co. it is necessary to haul the ore around the mountain a distance of a mile to get to the plant, although in a direct line it is only $\frac{1}{2}$ mile. The deposit has been opened along the side of the mountain for 300 ft. and shows a face 45 ft. high. Holes have been put down at different places back of the face showing a solid block for 200 ft. beyond the face. In this it is estimated there is \$750,000 worth of sul-

phur figured on a normal market of \$9 a ton, instead of \$34, as at present. The plant is making 20,000 lbs. of sulphur a day and has contracted for the entire output for some time. A cave filled with pure sulphur and containing about 300,000 lbs., which has a value of \$5000, has been opened. The find is within 400 ft. of the refining plant and the product can be shipped direct. The company has entered into an agreement for a lease on adjoining ground, which will mean a large saving in hauling charges, as the ground is but a short distance from the plant. On it are tracks and a mill that was built some years ago. It was a failure on account of the process. It is said that the plant cost over \$65,000. The property contains considerable sulphur that was formed as fumaroles. It is the intention to take up the present tracks and use them to haul the ore over to the plant.

CANADA.

BRITISH COLUMBIA.

Slocan.

"Owing to the fact that the water supply failed 6 weeks earlier than usual this season, the Slocan Star Co. has been greatly hindered in its operations by lack of sufficient power, for which reason both mine and mill are working only one shift," says Sidney Norman. "All the machinery for the new hydro-electric power plant, with the exception of the wheel and one length of pipe, has arrived and is being installed so that the plant may be got into operation within a few days. During August the company shipped 5 cars of silver-lead ore and concentrates, which netted \$16,000 above operating expenses of \$10,000. The zinc shipments, whose proceeds are not included in the above figures, totaled 110 tons.

"The Rambler-Cariboo has much larger reserves of ore than it is usually credited with. Mining operations are proceeding on the 8, 9, 10, 12 and 13 levels, from which 75 tons of ore are being sent daily. Shipments of lead ore and concentrates average around 175 tons a month and the mill also produces about 75 tons of 33% zinc concentrates. Of the latter product there is now about 1000 tons on hand awaiting retreatment in the Kaslo custom concentrator, where it will be worked up to a satisfactory shipping product. One stope above the 9th level shows 16 to 18 ft. of first-class concentrating ore with a streak of clean galena from 1 to 2 ft. wide.

"The Lucky Jim mine has developed much ore and by the recent completion of a raise from a crosscut from the No. 5 tunnel to the big stope is now in shape to produce economically. It is shipping high-grade mill feed only to the Roseberry concentrator and mine run to Kaslo. The latter averages 21% zinc, 1.3% lead and 16% iron. The preliminary runs of the magnetic separator at the Kaslo mill yielded a product assaying 46% zinc and between 8 and 9% iron.

"One of the finest ore showings I saw on my trip was that in the Sovereign mine, recently bonded by Clarence Cunningham, who is operating the Queen Bess and Wonderful as well and is about to take over the Idaho-Alamo, all four properties being now on a producing basis. The intermediate level on the Sovereign shows between 3 and 4 ft. of clean galena in the face and has proved the shoot for a length of 30 ft. At one point the clean ore is fully 5 ft. wide. There are 70 tons of ore sacked and ready to ship to the smelter. In the Queen Bess Mr. Cunningham is mining an entirely new ore shoot on the 5th and 6th levels. Owing to its being in virgin ground it has a good chance of going to the surface and being found also at depth in the 9th level. It averages between 2 and 3 ft. of clean galena. He is shipping regularly also from the Wonderful.

"The new 100-ton mill being built by the Surprise and Ivanhoe companies jointly on the site near Sandon of the old Ivanhoe plant, which was destroyed by fire while treating Lucky Jim ore, will be in operation in a few weeks. The Ivanhoe tramway has been rebuilt and W. H. Yawkey of New York has resumed the development of that property, which is now in shape to resume production at any time. The ore bodies in the Surprise mine are large and clean. They are

opened to a depth of 1200 ft. below the apex of the vein in Surprise basin. The mine is managed by Alexander Smith, who has been financed entirely for 20 years by Congressman Charles Kent of California. The mine now contains vast ore reserves and netted \$180,000 last year.

"The Canadian group, adjoining the Ivanhoe, has been reopened and Bruce White has just let a contract to haul 100 tons of silver-lead ore from the Noonday mine at Cody to the railroad at Sandon. The Noble Five is working 3000 ft. below the apex of the Last Chance mine and is taking out a good grade of mixed lead and zinc ore."

Victoria.

The 1916 mineral production of British Columbia will be between \$45,000,000 and \$50,000,000, according to the estimate of Lorne A. Campbell, retiring minister of mines in the province, who probably is in closer touch with the mining industry in western Canada than any one else. "This is about \$15,000,000 in excess of the record of 1912, which was the best previous year in the history of British Columbia," says Minister Campbell, "and if the encouragement is given to the industry that is justifiable there is no doubt but there will be a gradual increase in the output for an indefinite period. The present increase is largely due to the increased prices consequent upon the enormous demand for the metals. This will prove a boon for mining in British Columbia in view of the fact that within the past year the industry has become equipped in a manner never before experienced. Large extensions to plants have been made, labor-saving machinery installed and the facilities for production vastly increased. A lot of new capital has been invested in the industry and more is seeking investment. Even if things do become normal practically all the large producers today are in a position to operate at good profits. The industry was never better organized than at present. The scarcity of labor has had a great effect in inducing the companies to instal up-to-date machinery and labor-saving devices."

MEXICO.

Cananea.

Despite the troubles it has encountered in Mexico the Greene-Cananea Co. has an excellent chance of showing increased earnings this year. The October output is expected to exceed 5,000,000 lbs., compared with 4,800,000 lbs. in September. When the American employees left the mine in June it was believed that the property would be obliged to shut down; but, nevertheless, 4,500,000 lbs. of copper was turned out in that month. While this represented a substantial decrease from the 5,948,000 lbs. produced in May, it showed that the conditions surrounding the property were not as serious as had been generally supposed. The June output was bettered in July by 100,000 lbs., while August showed an increase of 500,000 lbs. over the minimum monthly production of 3,348,000 lbs. in January. The production for the year is estimated at 60,000,000 lbs., and earnings should amount to \$10,800,000, equivalent to \$21.60 a share on the 500,000 shares of a par value of \$100 outstanding. Dividends are at the rate of \$8 per share per annum, so that earnings are 2.7 times dividend requirements, and the surplus after dividends would amount to \$13.60 a share, more than sufficient to pay another dividend and leave a handsome surplus besides. On a normal production of 6,000,000 lbs. monthly earnings would figure to over \$23 a share, or 44% on the present selling price of the issue. Four dividends paid out since January have called for \$2,846,460, leaving surplus earnings of about \$2,874,000 for the first 9 months. Including \$5,411,242 net surplus and cash assets as of Jan. 1, 1916, there remains a total of \$8,284,782. The current dividend rate of \$2 a share, expected to be continued at the meeting to be held the last week of this month, will call for the payment of \$948,822, leaving a surplus of \$7,334,960. The Greene-Cananea Copper Co. has an authorized capitalization of \$60,000,000, divided into 600,000 shares of a par value of \$100, of which \$5,000,000, or 500,000 shares, are issued and outstanding. The company has no bonded indebtedness.

World's Index of Current Literature

A Weekly Classified Index to Current Periodical and other Literature, Appearing the World Over Relative to Mining, Mining Engineering, Metallurgy and Related Industries, in Four Parts.

Part 1. *Geology*—(a) Geology; (b) Ore Genesis; (c) Mineralogy.

Part 2. *Ores and Metals*—(a) Metals and Metal Ores; (b) Non-Metals.

Part 3. *Technology*—(a) Mines and Mining; (b) Mill and Milling; (c) Chemistry and Assaying; (d) Metallurgy; (e) Power and Machinery.

Part 4. *General Miscellany* (including Testing, Metallurgy, Waste, Law, Legislation, Taxation, Conservation, Government Ownership, History, Mining Schools and Societies, Financial, etc.

Articles mentioned will be supplied to subscribers of *Mining and Engineering World* and others at the prices quoted. Two-cent stamps will be received for amounts under

\$1. Subscribers will be allowed a discount of 5 cts. if the price of the article exceeds 50 cts. The entries show:

(1) The author of the article.

(2) A dash if the name is not apparent.

(3) The title, in italics, of the article or book. Titles in foreign languages are ordinarily followed by a translation or explanation in English.

(4) When the original title is insufficient a brief amplification is added. This addition is in brackets.

(5) The journal in which the article appeared; also the date of issue, and the page on which the article begins.

(6) Number of pages. Illustrated articles are indicated by an asterisk (*).

(7) The price.

Difference in domestic and foreign prices explained by the fact that the New York quotations are per fine ounce; the London per standard ounce 8.925 fine.

Copper.—Expectations that business in copper would soon become desultory were considerably upset in the past week when business in large volume appeared, buying being vigorous and well spread out. Producers were surprised by the influx of business following a few days of comparative quietness, which they assumed was a prelude to a dull spell. Domestic consumers came into the market rather suddenly and took metal for the second quarter of next year, although a good business was also done for delivery this year and over the first quarter of next year. The fact that consumers who had already covered first quarter needs decided to buy for the second quarter without waiting for a possible reaction in prices was a pleasing sign to copper sellers who now feel confident that their own optimism is shared by consumers.

Some foreign orders have been placed since our last report. Italy has ordered about 2,500,000 lbs., while a miscellaneous foreign business amounting to about 1,000,000 lbs., has been booked. Transactions last week are estimated at 15,000,000 lbs.

Indications are that records in production, domestic consumption and exports will be broken this year. Refinery yield this month is expected to total 170,000,000 lbs. and with cold weather driving labor to indoor employment it is expected that output will increase steadily, so that by December a production of 190,000,000 lbs. will have been attained. On this basis, it is figured that the average monthly yield for this year will be 175,000,000 lbs., giving a production which may reach 2,100,000,000 lbs. Domestic consumption for the year is estimated at 1,200,000,000 lbs. and exports are reckoned at 900,000,000 lbs. While these are records that the trade will feel proud of, the fact remains that 1917 will bring new records. Refinery output early next year is expected to total 200,000,000 lbs. a month and with business coming in at a rate that assures the full absorption of this output over the entire year a production of 2,400,000,000 lbs., domestic consumption of 1,200,000,000 lbs. and exports of 1,100,000,000 lbs. are considered probable.

The price situation has shown no essential change in the

past week. Dealers have adhered firmly to prices, while producers are declining more business than they are accepting. Some dealers are entirely cleaned out for this year. Spot electrolytic holds at 29¼ cts., with November at 28¾ cts. and December at 28¼ cts. January is quoted at 28 cts., February at 27¾ cts. and March at 27½ cts., with first quarter contracts at 27½ cts. and second quarter at 27@27¼ cts. Casting copper is very scarce and leading makers are unable to take business for delivery before late November, for which position sales at 27½ cts. has been made. A few small spot lots sold at 28 cts.

The London market has been devoid of any spectacular movement. Electrolytic last week went up 10s to £143 10s, with gains of £1 in standard spot and £1 10s in futures.

Exports of copper since the first of October total only 16,785 tons, and unless southern and Pacific ports show large shipments the full month's total will be well under the exports of September, August and July.

Quotations for copper per pound at New York for the week ended Oct. 25 were as follows:

	Lake.	Electrolytic.	Casting.
Oct. 19.....	28½@29	28½@29	27¼@27½

Tin.—Irregularity has characterized the tin market since our last report, but it is apparent that there is strength underlying the market. Straits tin reacted to 40¼ cts. for spot, but subsequently recovered to 41¼ cts. Spot Banka held steady at 40½@41 cts. Little business was done in futures. The east has been very firm with the limits and few of the offerings were taken up. Straits tin for November and December delivery is quoted at 41 cts., with January, February and March arrival at 40¼ cts. and April and May arrival at 40¼ cts.

At London there was a soft spot during midweek, but the market came firmer toward the close.

Quotations for tin per pound at New York and per ton at London and Singapore for the week ended Oct. 25 were as follows:

Oct.	New York		London, Straits, spot.	Singapore, shipments.
	Spot.	October.		
19	41c	40¾c	£179 10 0	£183 15 0

Lead.—Quite a large business has been done in lead in the past few days. Canadian ammunition makers came into the market and took up options which producers had given them on about 2500 tons, while Far Eastern consumers bought 2000 tons. These purchases were the only developments of note in an otherwise drab market. Domestic consumers, being well covered, were not seeking metal. The market holds very strong, due to the sold-up position of all producers, while dealers are not large holders and are demanding the top price for the metal they control. Spot lead in the outside market held at 6.92½@6.95 cts. St. Louis, while spot New York was quoted at 7.20 cts. Producers took orders for November at a base price of 6.90 cts. New York, or 7.05 cts. New York with December delivery \$1 a ton less.

The London market has been dormant, prices holding unchanged for almost three weeks at £30 10s for spot and £29 10s for futures.

Quotations for lead per pound at New York and per ton at London for the week ended Oct. 25 were as follows:

Oct.	New York		London

Lead Ore.—In the Missouri-Kansas-Oklahoma district during the week ended Oct. 21 the market made further gains, as during the previous week, and ores sold as high as \$87, though in many cases only \$80 was obtained per ton for concentrates. The production for the week was 1,787,480 lbs. and was valued at \$76,482. The total for the year to date was 83,512,447 lbs., valued at \$3,458,421.

Zinc Ore.—Though the top price for zinc ores remained at \$70, as during the previous week, the range was only down to \$65. Concentrates produced during the week totaled 12,250,200 lbs., valued at \$403,250, and the total for the year was 531,377,490 lbs., valued at \$22,462,538.

Calamine.—The market was about in the same condition as during the previous week and ores sold at from \$35 to \$45.

December				87.00
Year				102.95

Spelter.—Galvanizers came into the market for spelter quite unexpectedly and the sudden activity caused prices to advance. A good business was done in prime western metal for delivery in the first quarter of next year. Brass makers were also in the market, but not to any large extent. Dealers who were active buyers a few weeks ago have been the principal sellers. Most of the important producers adhere to their determination not to dispose of first quarter output until November and December, when they expect better prices will be obtained. Spot prime western, after receding to 9¼ cts. New York, advanced to 10.30 cts. New York. The spot market at St. Louis was also very tight, holding only \$1 a ton lower than New York. Business in prime western for the first quarter was done from 9.50 cts. St. Louis up to 10½ cts. St. Louis, the higher price prevailing at this writing. No foreign demand was noted. Sellers of brass special reported

a fair domestic demand with the market steady at 11 cts. St. Louis for spot.

The London market declined early last week, but recovered slightly toward the close.

Quotations for spelter per pound at New York and per ton at London for the week ended Oct. 25 were as follows:

MISCELLANEOUS METALS.

Quicksilver.—There has been no change in the situation in this metal. Sellers report a fair business moving, with the price holding at \$80 per flask for spot virgin. A more active demand from powder makers is expected, some very large contracts for gunpowder now pending, both for foreign and domestic account.

Platinum.—Refiners reported a steady demand from jewelers, with the market holding at \$90 for soft and \$96 for hard metal.

Tungsten.—Business continues very dull. Consumers who loaded up tungsten when the price was around \$90 a unit are so well supplied that they are not likely to enter the market for new supplies until next January. Producers in the meantime are accumulating stocks. Some small producers who are in need of money have been offering ore at \$16 per unit and requesting counter bids, which indicates that they would accept \$14 per unit delivered New York. The important producers, however, are holding for \$20@25 per unit and expect to secure that price, pointing out that the marked activity in the steel business means a large consumption of tungsten.

Antimony.—The market has been quiet, but prices are being maintained by sellers, who report that stocks here have been eliminated by the recent sales to Canada and Italy. Domestic producers, however, are holding spot metal, on which they are asking 13 cts.

Nickel.—The situation continues as previously, sellers reporting a fair demand, with prices repeated at 45 cts. for ordinary forms and 50 cts. for electrolytic.

Ferromanganese.—Selling of ferromanganese by the Carnegie Steel Co. and another producer in eastern Pennsylvania at prices lower than those asked by merchant producers has upset the market. The Carnegie company has done business at \$162 delivered, while merchant producers have been quoting \$166 delivered. British makers continue to quote \$165 seaboard.

Pig Iron.—The upward movement in pig iron prices continues. Bessemer of special analysis has sold at \$26 valley, while standard bessemer is strong at \$24 valley. Basic has sold at \$21 valley, with some dealers asking \$21.50 valley. Foundry grades are also advancing. Birmingham furnaces have sold spot No. 2 iron at \$16 furnace and are holding

first half iron at \$15.50 Birmingham. Virginia furnaces announced another advance to \$18.50 for No. 2 iron. Buying, both foreign and domestic continues active.

Manganese Ore.—Demand for this ore for blast furnace use has been rather quiet in the past week. Leading importers report that business in Cuban ores has fallen off considerably, recent importations showing high silicon contents. Cuban ore, 40% metal contents, is quoted at 55@58 cts. per unit, while ores lower in silicon are quoted at 65@70 cts. per unit at the seaboard. Chemical ore is quiet at 4½ cts. f. o. b. New York.

No. 19. Vol. 45.

CHICAGO

November 4, 1916.

The Formation and Achievements of the American Mining Congress

The American Mining Congress was organized 19 years ago, at the height of the agitation for free silver coinage. In Colorado, where mining men felt the great need of co-operation in matters pertaining to the industry which had just received its most serious setback, the idea was born. And, strange to say, its first rather indefinite purpose was to have a "Gold Mining Convention." Over in Gilpin county, where vast fortunes both in silver and gold had been taken out of the ground, there at the home of the late Senator Henry M. Teller, the greatest of "silver" zealots, were men who believed that "gold was also an important factor in the economy of the world." In fact, all over the state there was this feeling of getting down to business on a "gold mining" basis.

International Mining Congress Formed.

And on July 7, 1897, the delegates assembled in Denver and elected former Governor Alva Adams as temporary chairman. The representation was excellent. When the inevitable free-coinage resolution had been debated, when all the rancor of the previous 2 years of free silver discussion had been fairly well boiled out of the convention, the delegates started in to do something tangible for the mining industry. It was termed the International Gold Mining Congress, and under this name it labored for 5 years.

At the very outset it gave itself the task of agitating for the creation of a federal department of mines and mining. The resolutions adopted had the right ring, but no concerted effort was made to put them into effect. The second meeting of the convention was held in Salt Lake City, former Governor L. Brandford Prince of New Mexico presiding. The honor of the first actual presidency had been given him at the Denver convention.

The third convention of the Congress was held in Milwaukee in June, 1900, Col. B. F. Montgomery, of Cripple Creek, former Lieutenant-Governor of Colorado, presiding.

In 1901 in the convention at Boise, Idaho, Governor Prince was again chosen president. The fifth convention was held at Butte, Mont., and all of the movements which had received previous endorsement were again made a prominent feature.

These early years of the Congress comprised its formative epoch. The best mining men of the country, men who knew what was needed to rehabilitate the industry, took an interest in the affairs of the Congress. At the sixth annual convention, which was held at Deadwood and Lead, S. D., Hon. J. H. Richards presided.

Becomes American Mining Congress.

As a matter of fact the real history of the American Mining Congress, the period of effective labors, begins with the Portland convention in 1904.

Now it was that the great mining engineers of the country began to take part in its deliberations. Government experts appeared at conventions with important papers. In 1904 for the first time the president of the United States was persuaded to appoint delegates. Great men now proffered advice, and realized that only by such co-operation as the Congress furnished could the mining industry be uplifted, and made a great power in the United States. Men like Charles W. Goodale, S. A. Taylor, James W. Malcolmson, Dr. James Douglas, D. W. Brunton, Hennen Jennings, John Hays Hammond, J. R. Finlay, J. Parke Channing, Edward B. Kirby, S. W. Mudd—to mention only a few of the many prominent engineers who are now among its most active members—took a hand in its deliberations. From this time on the resolutions passed by the Congress were accepted by legislatures and by both houses at Washington, as authoritative in the mining world.

Hon. J. H. Richards continued as president during the sessions at Portland in 1904; at El Paso, Tex., in 1905; at Denver, in 1906; at Joplin, Mo., in 1907, and Pittsburgh in 1908, and at Goldfield in 1909.

In 1904 at the Portland convention James F. Callbreath became secretary and permanent headquarters were established at Denver. The American Mining Congress now became a tremendous factor in the development of the mining industry of the country—perhaps the greatest factor.

Demand for a Bureau of Mines.

Out of the early propaganda for a mining department came the more practicable demand for a Bureau

of Mines. Of this the late Dr. J. A. Holmes, who was its first director, said at the meeting following the establishment of the bureau:

"This movement for appropriate recognition and aid for the mining industry from the national government has been under way for many years. Among its early and most active supporters have been the California Miners' Association and the American Mining Congress. It is, therefore, eminently appropriate that at the first session of the American Mining Congress, following the creation of the Bureau of Mines, at a session held in California, something should be said of the policy and purposes of the new Bureau."

And in outlining these purposes Dr. Holmes expressed the thought that he would continue to lean heavily upon the American Mining Congress for the expression of what would be best for the mining industry in the future. It was at the sessions, and from the men in charge of the work of the American Mining Congress, that he hoped to get his inspiration for the labors which were so close to his heart.

But the history of the American Mining Congress can now best be told in the great utterances of its leaders, in the splendid committee work, in the resolutions passed, and in the determination to accomplish what had been resolved upon.

History is never a mere narrative of meetings and elections. It is, or rather should be, a chronicle of the spirit of co-operation by which men uplift themselves as well as their industry.

At the meeting of the American Mining Congress in Joplin in 1907 Dr. J. A. Holmes made this epochal utterance:

"We are going to ask the American Mining Congress to march into the coal field and capture the help of the mining interests in the central portion of the United States. Then with the concentrated effort on the part of the mining men from all sections of the country, we may be prepared to obtain the co-operation and help from both the federal and state governments to which we claim the mining industry is entitled. We are today using up our mineral resources so rapidly that we are consuming both our own share and the share belonging to the future. We are dealing with great national problems as never before in the history of our mineral development; and we must consider and solve these problems in a true national spirit. In this connection the American Mining Congress must capture the east and the south as it has the west. Let us, therefore, hold our next two meetings, one in the heart of the Mississippi Valley coal fields, and another in the heart of the Alleghenies, probably at Pittsburgh. We will thus gain in eastern membership and influence and will become truly representative of the great American mining industries. We will then the more easily accomplish the great national purposes for which we have our being."

Impromptu as was the utterance, it was in a way climactic. For, true to his prediction, the next meeting was held at Pittsburgh, and the east opened its heart to the Congress. In fact, within 2 years, and by reason of the tremendous help given the original idea by the coal interests of the country, Congress passed the act creating the Bureau of Mines.

The successful battle on the flotation of worthless mining stock by unscrupulous promoters took definite shape at this meeting.

At this time also the objects of the American Mining Congress had crystallized into clear-cut issues, all of them of vast importance to the mining interests of the country. These had been carefully prepared by

the officials and President Richards, in reading them, said: "These summarize just what was presented to Secretary Garfield and what seemed to him to justify us in our claim to the right to a department."

"We believe the mining industry will be greatly aided:

"(1) By the granting of continued and larger appropriations for the investigations by the Geological Survey, so that the results may be reached rapidly enough to more nearly meet the growing needs of the country, including:

"(a) The classification of the public lands;

"(b) The exploration, surveying and mapping of the geological formations, ore bodies, mineral deposits, etc.;

"(c) The investigations of the nature, extent and origin of these deposits and of the origin of the coals of the country.

"(2) By the establishment at this time of a Bureau of Mines, with ample authority and funds for the investigation of and inquiries into:

"(a) The methods and processes employed in the mining and quarrying industries and in the handling and treatment of mineral products with a view to aiding these industries, preventing mine and quarry accidents, and recommending appropriations;

"(b) The wise utilization and conservation of the mineral resources through the prevention of waste, the development of more efficient methods, etc.;

"(c) The mining conditions, and the most efficient methods for the handling, treating and using of ores and other mineral products in foreign countries, with a view to benefiting American mining, quarrying and other mineral and metallurgical industries;

"(d) The publication, in such form as to be really available, of the information obtained from all these investigations and inquiries; the wide and prompt distribution of these publications among the mining men of the country; and co-operation of impartial government experts in this educational work by public addresses in mining camps and at the meetings of men associated with mining and quarrying industries, with a view to the prevention of accidents, the preventing of waste, and more efficient work.

"(3) The above action is recommended with a view to the establishment from time to time of other allied bureaus and ultimately the establishment of a Department of Mines if the conditions may warrant such action.

"(4) By revising existing legislation relative to mineral lands and mining:

"(a) To provide for the separation of surface from underground ownership, with a view to the independent development of the mining and of the agricultural or forest industries;

"(b) To prevent fraud in the entries made to and patents obtained on mineral lands; and

"(c) To facilitate the disposition of these lands by lease, sale or otherwise, under such conditions as will best facilitate legitimate and practical mining."

President Richards announced that when these were presented to Secretary of the Interior Garfield he said: "I think you are entitled to a Bureau," and President Roosevelt promised a definite recommendation in his next annual report.

Thus was the great struggle securing friends—through the endless presentation of facts, through the persistent pounding of great and determined men upon the doors of the departments and of Congress. For even at this session a message was sent to the president thanking him for what had been done and forcibly reminding him of his promise.

At the session of 1907 George Otis Smith, director of the U. S. Geological Survey, presented an important paper on "The Possibilities and Limitations of Geological Survey Work as Applied to the Mining Industry," and Edward Goodrich Acheson, the discoverer of a method for the manufacture of car-

borundum, discussed some of his remarkable experimental work in the production of crucibles from artificial graphites. At this session, too, the work of all the mining schools of the country was thoroughly gone into and the first steps were taken to secure

became an historical fact. For the coal men not alone participated in the proceedings but joined their problems and their energies to what, while national in scope, had up to this time been a purely western organization. At Pittsburgh the American Mining Con-

government aid for experimental work in mining states.

First Session Held in the East.

In 1908 the American Mining Congress invaded the east, holding a session in Pittsburgh from Dec. 2 to 5. And here the inspired prediction of Dr. Holmes

gress, in its membership, and in its activities, put on the purple toga of nation-wide co-operation.

Safety Legislation Demanded.

At the Pittsburgh convention the American Mining Congress definitely planned what, up to this time,

THE LATE DR. E. R. BUCKLEY.

President, 1910.

had been but a tentative program, for the most stringent possible "safety" legislation.

The fact brought out that in 1907 3000 miners were killed in accidents, an increase of 50% over the record of 1906, brought home to the convention the need of the most drastic action.

Congressmen J. F. Burke of Pennsylvania and John C. Chaney of Indiana and Senator Charles Dick of Ohio took an active part in the proceedings at Pittsburgh, and were the sponsors for the measures which were later drafted into law, and which had been brought up and discussed at the meeting of the American Mining Congress at Pittsburgh.

It is appropriate at this point to add that the impetus given for the enactment of "Safety" measures at the Pittsburgh convention was far-reaching in its influence. Here is record that speaks for itself:

Year.	Production (short tons).	Employed.	Killed.	Rate per 1000 empl.	Killed per million tons.
1907.....	480,363,424	680,492	3,242	4.81	6.78
1908.....	415,842,698	690,438	2,445	3.60	5.97
1909.....	460,814,616	666,552	2,642	3.96	5.73
1910.....	501,596,378	725,030	2,821	3.89	5.62
1911.....	496,371,126	728,348	2,656	3.65	5.35
1912.....	534,466,589	722,662	2,419	3.35	4.53
1913.....	570,048,125	747,641	2,785	3.73	4.89
1914.....	513,525,477	763,185	2,454	3.22	4.78
1915†.....	518,000,000*	767,553†	2,264	2.95	4.37

*Estimated by U. S. Geological Survey. †Subject to change.

Meantime, acting on the humanitarian impulse created by this movement, many large industrial and railroad organizations have created special "Safety-First" movements, through which marvellous results are being obtained in the way of preventing accidents.

It is interesting in this connection to note that one of the sessions of the American Mining Congress was held at the Government Station for investigation of mine explosions, which on that day, Dec. 3, 1908, was formally opened. Hon. James R. Garfield, Secretary of the Interior, delivering the dedicatory address.

The Pittsburgh Meeting.

The proceedings of the Congress at Pittsburgh commanded world-wide attention. Among the notable papers read were the following: Relation of the Federal Government to Mining, by Senator Charles Dick, of Ohio; Transportation of Mineral Products, by Edward H. Harriman; The Importance of Arbitration as a Factor in the Advancement of the Mining Industry, by Carroll D. Wright; The Federal Government in Its Relation to the Mining Industry, by Secretary of the Interior James R. Garfield; Problems of the Coal Mining Industry, by Dr. J. A. Holmes; Conservation in the Coal Industry, by John Mitchell; Arbitration as a Factor in the Mining Industry, by Judge George Gray, of Delaware, and Thomas H. Lewis, president of the United Mine Workers of America; and Distribution of the Nation's Mineral Wealth, by George Otis Smith, director of the U. S. Geological Survey.

Goldfield Meeting.

The twelfth annual session of the American Mining Congress was held at Goldfield, from Sept. 27 to Oct. 2, 1909, Judge J. H. Richards presiding. At

this meeting Secretary Callbreath announced the first great advance in the movement to establish a Bureau of Mines. "During the sixtieth Congress," he reported, "a bill was introduced in the Lower House for the creation of a Bureau of Mines, and passed by that body by a vote of 229 to 21. The bill was approved by the Senate Committee, but was talked to death in the final hours of the session. We will have to begin our work all over again."

And the Congress went on record again with a determination to win out at the next session.

Among the notable addresses at the Goldfield gathering were the following: National Problems, by Hon. Francis G. Newlands, of Nevada; Silver and the National Government, by Judge C. C. Goodwin, of Salt Lake City; Inspection of Mines, by Dr. J. A. Holmes; The Mining Men's Interest in Land Classification, by George Otis Smith.

Los Angeles Meeting.

Dr. E. R. Buckley, of Rolla, Mo., head of the Missouri School of Mines, took the presidency at the Thirteenth Annual session, which was held at Los Angeles from Sept. 26 to Oct. 1, 1910. And at this Congress Dr. J. A. Holmes delivered his first public address as head of the newly created Bureau of Mines.

But the creation of the Bureau of Mines was a task that had its ramifications, and the Congress at Los Angeles lost no time in formulating by resolution much of the work it expected the new bureau to accomplish.

This covered a wide latitude from effective safety measures for both coal and metal mines, to a most comprehensive exploitation of the underground resources of the United States. It meant, moreover, that the Congress must put its shoulder to the wheel and urge the largest possible appropriation for effective work.

It was at this session of the Congress that the movement for a thorough revision of the mining laws of the country was given a decided step forward.

But the most important report submitted was that of the Committee on Prevention of Mine Accidents. Its recommendations became of international interest, and have since been incorporated into the statutes of many of the mining states of the country. The committee consisted of Walter R. Ingalls, chairman, J. Parke Channing, James Douglas, James R. Findlay and John Hays Hammond. It was first appointed by the American Mining Congress in 1906, reported progress in 1907 and 1908, and in 1909 was given permission to submit its report to the American Institute of Mining Engineers and to the Mining and Metallurgical Society of America, as well as to the American Mining Congress.

This committee collated the mining laws of all the states and of foreign countries, and from a study of these compiled the now famous model statute "Relating to Metalliferous Mines, and to provide for the health and safety of persons employed in and about

the same." It gathered all available statistics on fatal mine accidents, and clearly established what had up to this time been only suspected, namely, that the loss of life in metal mining in the United States is fully as great as in coal mining. One of its most important recommendations, and which resulted in greater state appropriations through the west, was the concluding paragraph in its report on mine inspection:

In the opinion of the committee, the essential steps toward reducing the loss of life in metalliferous mining are (1) a comprehensive and effective law; and (2) an adequate system of mine inspection. The latter is the keystone of progress. Much can be accomplished by an adequate system of mine inspection, even if a comprehensive law be lacking, but no matter how thorough and effective in theory a law may be, it will fail in its purpose unless provision be made for its sincere, impartial and positive enforcement by an adequate system of competent mine inspection.

To secure such a system of mine inspection, the states must appropriate a good deal more money than any has yet done. Each state must have a mine inspector, and he must be provided with a sufficient number of deputies to enable frequent inspections of all operating mines to be made. One inspection of a mine in a year is not enough. The inspector and deputies must, moreover, be provided with proper funds for clerical work, traveling expenses, etc. So far as we are aware, the state of Colorado makes the largest appropriation for inspection of metal mines, its appropriation being \$25,000 per year. Other important mining states appropriate only \$10,000 per year. In the opinion of the committee, such appropriations are utterly inadequate. For states possessing a mining industry of the importance of that in Colorado, Utah, Montana, Nevada, California, and, in fact, all of the states and territories west of the Rocky mountains, an annual appropriation of \$50,000 to \$100,000 per state is necessary. Such expenditures are thoroughly justified by the importance of the end to be gained.

At this session of the Congress another important report was that of the committee on "Standardization of Electrical Equipment in Coal Mines." The proposed code of rules presented at this time, and as revised at the following sessions, have since been incorporated in the statutes of many of the states.

Among the notable addresses at this session were the following: The Bureau of Mines and Its Work, by Dr. J. A. Holmes; Proposed Legislation for the Disposition of the Public Lands, by Hon. Richard A. Ballinger; Shall We Have Private Ownership or a Leasing System, by Hon. F. W. Mondell; Conservation as It Affects the Oil Industry, by Hon. Gifford Pinchot.

Chicago Meeting.

The fourteenth annual session was held in Chicago, from Oct. 24 to Oct. 28, 1911, Hon. John Dern, of Salt Lake, presiding. The event of greatest import was the presence at this session of Hon. William H. Taft, President of the United States, who spoke on the topic: The Government and the Mining Industry. M. Jean de Pulligny, director of the French Mission of Engineers to the United States, was another notable guest whose address to the convention covered conditions of mining abroad. England and Canada also had prominent representatives in attendance who participated in the discussions.

The subject of Workmen's Compensation Law was ably discussed, the report of the committee on that topic furnishing the basis for most important legislation.

At this session steps were taken to establish headquarters in Washington, and the by-laws were amended to permit of an extension of the work by admitting to membership coal mining organizations or kindred bodies. These changes have been of great import in the history of the American Mining Congress. By establishing its headquarters in Washington the Congress was able to keep in close touch with federal legislation on all mining subjects, to suggest measures approved by the conventions and to oppose whatever might be deemed injurious to the industry.

Among the notable addresses at this convention in addition to those already mentioned were the following: The Public Land Question, by Governor William Spry, of Utah; The Past, Present and Future of Copper, by Horace J. Stevens, of Houghton, Mich.; The Economics of the Coal Industry, by Carl Scholz, of Chicago; What the West Needs in Coal Land Legislation, by Dr. George Otis Smith, of Washington; Alaskan Problems, by Hon. Walter L. Fisher, Secretary of the Interior, and The Relation of Congress to the Mining Industry, by Dr. Martin D. Foster, chairman of the House Committee on Mines and Mining.

Spokane Meeting.

The fifteenth annual convention of the Congress was held at Spokane, Wash., from Nov. 25 to Nov. 29, 1912, Samuel A. Taylor, of Pittsburgh, presiding.

The detailed report of the Committee on Standardization of Electrical Equipment in Metal Mines was submitted at this session, and is today considered an authoritative document in the compilation of legislation on this subject.

Among the notable addresses at this session of the Congress were the following: The National Forests and Development of Natural Resources, by Henry S. Graves, United States Forester; The Washington Compensation Act, by John H. Wallace, of Olympia, Wash.; and The Leasing of Mineral Lands, by William Griffith, of Scranton, Pa.

Philadelphia Meeting.

In 1913 the American Mining Congress held its sixteenth annual session at Philadelphia from Oct. 20 to Oct. 24, David W. Brunton, of Colorado, presiding. The question of a revision of the mining laws of the country, which had been agitated during successive Congresses, was now taking more definite shape. The co-operation of the American Institute of Mining Engineers and of the Mining Metallurgical Society of America was announced, and it was hoped that the three bodies acting together would obtain the long-sought-for legislative reforms in Congress.

Among the notable addresses at the Philadelphia Convention were the following: Relation of Big Business to Industrial Property with Special Reference to Mining, by Dr. Charles A. Van Hise, president of the University of Wisconsin; Conservation from the Western Standpoint, by Senator John F. Shafroth, of

Offices of American Mining Congress, in the Munsey Building, Washington, D. C.

(1) Reception room. (2) Publicity Department. (3) Secretary C. P. Breath at his desk. (4) Filing Department. (5) Assistant to the Secretary, Mrs. Coombes.

Colorado; Needed Changes in Our Mineral Land Laws, by Senator Thomas J. Walsh, of Montana; Arbitration as a Factor in the Mining Industry, by Wm. B. Wilson, Secretary of Labor; The Public Land Laws, by Assistant Secretary of the Interior A. A. Jones; Our Radium Resources, by Charles L. Parsons, Chief of the Division of Mineral Technology, Bureau of Mines; The Federal Government and the Mining Industry, by Hon. M. D. Foster, chairman of the House Committee of Mines and Mining; Lessons of the Year in Our Mining Industry, by Dr. Joseph A. Holmes, director of the U. S. Bureau of Mines.

Phoenix, Ariz., Meeting.

The seventeenth annual session at Phoenix, Ariz., held from Dec. 7 to Dec. 11, 1914, was presided over by Carl Scholz, of Chicago, and was marked by the last appearance at its session of the late Dr. Joseph A. Holmes, director of United States Bureau of Mines.

His remarks, brief as they were, had all the brilliancy of the past. He had traveled a long distance to be at these sessions, which, to his far-seeing mind, formed the basis for all the success achieved in the establishment of the Bureau of Mines, and for whatever it could do in the future. Here he felt he was in touch with the mining men of the country, the working and the operating classes, the men who knew what was best for the industry. And so he came to speak when he was physically too weak to make such an effort. He had a message to deliver, but could not complete it, and, only when a friendly point of order was raised, did he consent to take his seat. But these last remarks before the American Mining Congress contain a message of work, of duty yet to be performed. He said:

Since the Bureau of Mines was organized there has been comparatively little increase in the moneys appropriated for the actual investigations of mining, consequently we have not been able to do the amount of work which we would like to have done. Our plans for the present year are in no way enlarged upon those of the past year. Now, that is a condition which is going to continue as it is now until the mining people of this country make up their minds to the fact that they are not being treated on the square. You realize this very interesting information brought out by the President in his address the other evening, that whereas every miner in this country contributes something like \$1800 a year to the national wealth, as compared to \$800 or \$900 contributed by every farmer of the country to the national wealth, at the same time the people of the United States contribute 28 to 30 cts. per capita for the advancement of agriculture and less than 2 cts. per capita to the advancement of mining; that in spite of the fact that mining is the most hazardous of our great industries and agriculture is the safest; that in mining we have one lot of mineral resources, and that when they are gone the nation must depend upon something else or some other country, whereas agriculture is a self-perpetuating industry. Why is it that it is so difficult to get anything done out of the federal or state treasury on behalf of mining? And the first reason which I found in talking with members of Congress is the fact that when you talk to them about helping mining, what they see is the Homestake and the Treadwell and the United Verde and half a dozen great big mines in the country, and they say: Why, those fellows are rich enough to take care of themselves. They don't see the small miners of the country; they don't see the struggling miners who are trying to build up a great industry, and the reason they don't see these things is because they are not presented to them; and in that connection I want to emphasize one of the most important lessons for this session of the Mining Congress to learn thoroughly, and that is that until

the mining people of this country do what the railroad companies of the country are doing, educating public sentiment as to what the great industry is, and what it means to this nation, the people of the United States will never understand it.

The letter from Hon. Woodrow Wilson, President of the United States, was in a way a keynote for the work of the Congress:

"It will always be a tribute to your foresight and energy," he wrote, "that this new Bureau of Mines in the short period of its existence, with the kindly co-operation of state and other agencies, has been able, by persistent and intelligent effort, to turn an isolated, local movement for greater safety into a great national movement for 'Safety First' that has already gone beyond the mining industry into every industry of the country. I venture to say that thousands of lives have been saved by that movement and that many thousands more will be saved in the future.

"Gratifying as the results of this life-saving campaign may have been, however, there is still vigorous work for your Congress to do. I am informed that during the last year more than three thousand men were killed and a hundred thousand injured in the mining and metallurgical industries of the country. * * * I suggest this situation as an opportunity for further endeavor on your part to cut down this excessive toll of death and injury."

At this session a decided advance was made in formulating the views of the country on mine taxation, and on mine law revision, and putting both these topics into statutory shape.

The first steps were also taken to establish as an adjunct to the American Mining Congress a Bureau of Mining Economics, which is to gather information covering every phase of practical mining, which is to keep in touch with markets, with production, with legal decisions, etc., etc. This movement is still under serious consideration and is making good headway.

San Francisco Meeting.

The eighteenth annual convention was held in San Francisco from Sept. 20 to 22, 1915, President Carl Scholz presiding. The notable event of the gathering was the Holmes memorial service, at which a vast host of admirers and friends paid tributes to the work and character of the late director of the U. S. Bureau of Mines.

All of the great problems which had come before the American Mining Congress in past sessions, and still needed settlement, were carefully discussed, and prepared for presentation to state and national legislative bodies.

Among the notable addresses at this convention was that by the successor of Dr. Holmes as director of the Bureau of Mines, Hon. Van H. Manning. His presentation of What the Bureau of Mines in the Department of Interior Is Doing and Hopes to Do for the Metalliferous Mining Industry, was masterful and comprehensive.

Other notable addresses at this session were the

following: Plain Writing, by Dr. George Otis Smith; Prejudice Against Regulation, by Rush C. Butler; California's Water Infiltration Law, by Fletcher McN. Hamilton; Federal Control of Water Power, by Hon. J. H. Richards; The Need of Better Mining Education, by Charles F. Willis; The Development of Mine Taxation in Arizona, by G. H. Dowell; Workmen's Compensation Insurance and the Coal Mining Industry, by Herbert M. Wilson; The New Plan of Mining Insurance, by David Ross; Mining Hazards on the Pacific Coast, by Dr. Frederick L. Hoffman; and Future of the American Zinc Industry, by Otto Ruhl.

The More Intimate Work of the Congress.

This history of the American Mining Congress is compiled largely from the records of the conventions held from year to year, and to a great extent, and necessarily, bridges over an immense amount of labor done by officials and committees between sessions. But it would not be a history in any sense if it did not include as far as this is possible some mention of what one must call the more intimate work of the congress.

When James F. Callbreath was elected secretary in 1904 at the Portland convention, the Congress felt that its influence must not begin and end with annual discussions and resolutions. Here were the expressions, the sentiments, here was the consensus of opinion of the mining men of the country. It was imperative that these recommendations should be shaped into laws, both state and national, and to the secretary was given the task of driving home, so to speak, the determinations of the Congress. How well the task was done, how brilliantly and conscientiously the pur-

poses of the mining congress were brought to the attention of the law makers of the land, is best attested by the results. The task was in many respects Herculean, for there were vast interests opposing every progressive movement of the Congress. And it was sheer grit and a gripping persistence on the part of the officials of the Congress and the men who worked with them in the intervals between conventions, that wrested from legislators, state and national, important reforms that have bettered the working conditions in the mines, have saved the lives of thousands of workmen, changes that have made mining investment safe and stable, new laws that have uplifted the mining industry of the country.

And the work of preparing for the conventions, of mapping out programs, of securing speakers of note, of interesting a greater number of mining men in the co-operative work of the Congress, all the vast details, preliminary work, has been done by Mr. Callbreath with rare zeal and intelligence, and is reflected in a constantly growing organization and in more and more interesting and instructive conventions.

In 1913 Carl Scholz, of Chicago, was elected president of the American Mining Congress. He was re-elected at both the following conventions, and without reflecting on the many capable executives of the past, it is but just to him to say that no one has had the welfare of the Congress more at heart, no one has ever served it with a greater zeal for the advance of the mining interests in America. No task in behalf of the industry proved too arduous for him to undertake, and no executive has ever carried out with greater skill and with more success the determinations of the Congress.

A Distinguished Gathering at the Chicago Meeting, 1911, Ex-President Taft in Center.

What Will be Done at the Chicago Meeting

On Nov. 13, when the nineteenth annual session of the American Mining Congress opens at Hotel La-Salle, Chicago, there will be in attendance a delegation from every mining state in America, and representatives from nearly every important mining section of the country.

President Wilson has notified Secretary J. F. Callbreath of his appointment of the following delegates: E. H. Benjamin, Oakland, Cal.; H. M. Chance, Philadelphia; Curtis H. Lindley, San Francisco; James MacNaughton, Calumet, Mich.; Van H. Manning, Washington; E. P. Mathewson, Anaconda, Mont.; Charles Piez, Chicago; W. L. Saunders, New York; George Otis Smith, Washington; A. H. Woodward, Woodward, Ala.

E. H. Benjamin was for many years the president of the California Mining Association, and is one of the great mining engineers of the country.

Dr. H. M. Chance, of Philadelphia, is also a noted mining engineer and one of his activities at present is the working out of the engineering features for the production of iron ore in northern New York. Curtis Lindley is the author of "Lindley on Mines," the accepted standard among mining lawyers on matters pertaining to mining law. James MacNaughton is the vice-president and general manager of the Calumet & Hecla Mining Co. E. P. Mathewson has been prominent in the Anaconda Copper Mining Co.'s metallurgical affairs. Charles Piez is president of the Link-Belt Mfg. Co., of Chicago. W. L. Saunders is president of the Ingersoll-Rand Co., past president of the American Institute of Mining Engineers, and at present on the President's Naval Consulting Board. Van H. Manning is director of the U. S. Bureau of Mines. Dr. George Otis Smith is director of the U. S. Geological Survey. A. H. Woodward is a noted southern mining engineer and at present general manager of the Woodward Iron Co., of Woodward, Ala.

The conference of coal mining men from the middle west called by Governor Dunne will be held in conjunction with the Congress and its conclusions, particularly in matters pertaining to uniformity of laws, will be of national interest.

Wherever possible the railroads have granted a special rate. In the Western Passenger Association territory, where the rates approximate 2 cts. a mile, no further concessions are made to any gatherings. From California and Pacific coast common points the information is given out that the nine-months' tourist rate of one and one-third fares to Chicago and return applies for the period of the sessions of the American Mining Congress.

The Central Passenger Association, which covers common points in Illinois, Indiana, Ohio, Pennsylvania, West Virginia, Michigan, eastern Missouri, western New York, has made a 2-ct. rate each way.

These tickets will be sold Nov. 11, 12, 13, and have a return limit to Nov. 20. Holders must reach original starting point before midnight of Nov. 20.

The special sessions in the interests of a western "Public Lands" policy will form a most important part of the Congress. The responses received and the delegates already appointed indicate that 12 and possibly 14 states will participate in the conference.

Governor Geo. W. P. Hunt, of Arizona, in his letter says: "This matter is of such importance that it merits serious attention from each of the western states."

Governor Kendrick, of Wyoming, is "of the opinion that such a convention will do much to bring to the attention of the press and public this important work."

"The great difficulty," says James F. Callbreath, secretary of the American Mining Congress, who is organizing the conference, "has been that the west has had no comprehensive policy, and even western representatives in Congress could not get together upon an intelligent plan for handling this question. The conference will be the means through which we will arrive at a practical solution of the public land problem.

"The belief that the resources which are essential to industrial prosperity should not be permitted to pass beyond public regulation must be considered, but it must also be recognized that the individual states must have the benefit of their own natural resources.

"In view of the present legislative situation at Washington, I feel that the conference is opportune and that it will begin a campaign to reopen mineral resources to development, to protect the interests of the states, to meet the eastern criticism against fuel and power monopoly and to work out the conservation that stands for the highest use and the least possible economical waste of the great mineral resources of the west."

The exhibit, which will take up the 17th floor of the hotel with the exception of two meeting rooms, is now an assured success. Arizona has taken two of the larger spaces for its exhibit. The University of Illinois is preparing a fine educational photographic display. The U. S. Bureau of Mines exhibit now at Detroit, will, of course, be shown and will be one of the main educational features on the floor. H. R. Ameling, of St. Louis, has engaged one of the larger rooms to show twice or three times daily with moving pictures, the operations of the core drill.

Roebing, Goodman Mfg. Co., General Electric, Justrite Mfg. Co., Macomber & Whyte, Stephens-Adamson, Link-Belt, Electric Storage Battery Co. of Philadelphia, Stromberg-Carlson, G. L. Simonds, and the Tool Steel Gear & Pinion Co. all promise thoroughly representative exhibits.

The rooms for the section meetings are all spacious

Van H. Manning.

and light. These are to be held during the afternoons. Particularly interesting will be the discussions on topics pertaining to the oil industry. There will be several interesting papers on the oil resources of the country. In a letter congratulating the Congress on its "oil" program, Rear Admiral John R. Edwards, U. S. N., writing from his home at Bristol, R. I., to Secretary Callbreath, sounds a new note in the country's industrial "preparedness" program:

"The extensive oil shale deposits of the Rocky Mountain region," says the Admiral, "offer far-reaching possibilities to the industrial and maritime interests as well as to the military departments of the nation, and the action of the American Mining Congress in giving special consideration to the question is another instance where the engineer is preparing to render an inestimable service in promoting national defense.

"It is by no means improbable that the existing industrial supremacy of the United States may be imperiled if we lose our relative lead in oil production, and therefore who can measure the importance of the service that has been rendered even in the past 2 years by the mining engineers of the country in pointing out the extent and character of the oil shale deposits of the United States. For it is in the direction of the retorting and distillation of the vast areas of shales of minable thickness and commercial richness that we must look to retain our lead in the production of the commercial petroleum products. The development of these shale areas ought to be one of the industrial responsibilities of the nation. In this work the mining engineer ought logically lead the advance."

The convention promises in its program to make even the technical side of many important questions interesting. This, in addition to the moving pictures

Dr. Henry Mace Payne.

Dr. W. R. Whitney.

James D. Phelan.

J. C. McDowell.

Frederick Laist.

Hon. W. R. Allen.

of the "core drill" there will be a great mass of interesting still and action pictures in connection with the various educational exhibits. Dr. Henry Mace Payne's lecture on the frozen gravels of Alaska and Siberia will have some marvelous films to supplement the technical side of the discourse.

It is hoped to have some moving pictures showing the effects of "explosions" in the work of mining. Then, of course, there will be the moving picture of the big Mexican oil gusher, the Cerro-Azul, of Mexico, to be shown and lectured upon by E. L. Doheny, of Los Angeles.

The address of Dr. Willis R. Whitney, who has been doing some wonderful research work for the General Electric Co., promises to be an epoch-making feature. It is to be on the subject of the Necessity for Research Work in the United States. It is to be a clarion call for national aid such as is given to the great research laboratories abroad.

On the general subject of "Safety" which is to be the feature of the morning session Tuesday, the 14th, there will be several notable addresses. These will be followed by a discussion on the Responsibilities and the Duties of the Operator, the Miner and the Public.

For the general session Wednesday when the subject will be Efficiency in Mining Operations there will be on hand a group of the country's greatest experts. Van H. Manning, director of the U. S. Bureau of Mines, will speak on Federal Aid to Mining Efficiency. The Federal Trade Commission and the Mining Industry will be discussed by Chairman E. N. Hurley, of the Federal Trade Commission. Charles M. Mod-erwell, a member of the executive committee of the Congress, will have an interesting report to present from the committee on relations with the Federal Trade Commission.

For the general session on Thursday, the subject will be Conservation. On this day Dr. Whitney's ad-

H. G. James.

H. H. Stock.

Ralph Crewes.

dress which has already been mentioned will give occasion for a great deal of discussion. President Carl Scholz will speak on The Conservation of Property.

The Section meetings, many of the topics for which were published in our last issue, promise much in the way of information that will be of great value to coal, oil, zinc, lead, copper, and precious metal mining men.

The address of Ralph Crews, of Chicago, on the subject Co-operation in the Marketing of Coal is to be followed by a discussion to which the secretaries of leading American Coal Marketing Associations have been invited. A sufficient number of acceptances assure a most thorough review of the entire subject. In fact the interest in the matter is so great that the time of the debate will probably be extended.

The address on The Federal Petroleum Bureau, by H. G. James, of Kansas City, will be the occasion for a warm discussion in the oil section. Dr. J. C. McDowell's paper on Geology in its Relation to the Oil Industry, is one that will greatly interest men in the oil industry.

Frederick Laist's paper on Electrolytic Separation gives promise of some revelations of intense interest in the way of improved processes.

In the coal section the paper to be read by H. T. Willard, of Cleveland, on Co-operation will drive home some great needs of the coal industry.

Dr. F. G. Cottrell's paper on New Things in Science is awaited with considerable interest, as he is the scientist who has had much to do with the progressive work done in the past 2 years by the U. S. Bureau of Mines.

Van H. Manning, director of the U. S. Bureau of Mines, has notified J. F. Callbreath that the government exhibit at the convention will surpass any mine display yet made by the bureau. There will be a collection of 175 underground coal mining safety pictures, arranged in series, and a group covering the same idea in metal mining. The government's complete set of approved electric wire lamps will be shown—the approved gas detectors, and a complete set of rock-dusting pictures and drawings.

In mine rescue and first aid display there will be a set of Fleuss-Proto apparatus, the Bureau of Mines oxygen inhalator, the Bureau of Mines first aid cabinet, the Bureau of Mines surgeon's emergency chest and a floor plan of one of the new steel cars.

Mr. Manning, director of the Bureau, will be in attendance on the sessions of the Congress and with him will come the leading experts of the department.

The "Public Lands" conference will have as delegates the west's most representative men, including a group of Senators and Representatives, who promise to bear the message of the gathering direct to the halls of Congress.

The men who have been chosen as delegates are determined to formulate a western policy on this ques-

tion, which will give to every state the power to develop the vast resources which have, in a way, been locked up by federal regulations and enactment.

The letters received from the governors give a clear idea of the general trend of the conference. For instance Governor Withycombe, of Oregon, says that there is even in the west a group of men that proceeds on the assumption that the state is not fit to care for the resources God has given it, and that the only administration of them which can be equitable to public interest must be centralized in Washington.

Governor John B. Kendrick, of Wyoming, writes that he will "co-operate in every way," in the enunciation of a western policy on the "Public Lands" question and "is of the opinion that such a convention will do much toward bringing to the attention of the press and public this most important work."

Governor Lister, of Washington, was one of the first of the western governors to appoint his delegates.

Governor Emmett D. Boyce, of Nevada, announces that "it will give me great pleasure to name delegates from Nevada."

And Governor George W. P. Hunt, of Phoenix, Arizona, writes: "This matter is of such importance that it merits serious attention from each of the western states."

The American Mining Congress at the coming session plans to devote considerable attention to the oil industry. The general meetings are to be held in the mornings, and the sections devoted to oil, coal, lead and zinc, copper and precious metals, are to meet every afternoon in their own assembly rooms at the hotel. One of the special questions in the oil section will be that relating to the rights of the western oil claimants upon lands withdrawn from entry and upon which large development has been made.

But there will also unquestionably be an emphatic protest against policies of the government in the proposed creation of naval oil reserves, and more particularly against the policies which work gross injustice to oil claimants who located their claims and carried on development work under the provisions of then existing legislative conditions.

The assured success of the convention is due to a great extent to the splendid work of the local committee and the unstinting labors of the president of the Congress, Carl Scholz, of Chicago, and to Secretary Callbreath, without whom there would be no American Mining Congress today.

Mention should be made of the publicity bureau, which under the management of Alfred Patek, did splendid work this year. Mr. Patek was formerly publisher of the Denver Times, and has recently removed to Chicago where he will carry on a general publicity bureau.

The details of local entertainments are now being prepared. The banquet will be in every way notable. Luncheons and one or two excursions to neighboring plants are also under consideration.

Program Nineteenth Annual Meeting

GENERAL SESSION.

Monday, Nov. 13—2 P. M.

Convention called to order by Harry C. Adams, Chairman, Committee of Arrangements.

Invocation: Rev. Frank W. Gunsaulus, Chicago, Ill.

Address of Welcome: Hon. Edward F. Dunne, Governor of Illinois.

Address of Welcome: Hon. Wm. H. Thompson, Mayor of Chicago.

Address of Welcome: J. W. O'Leary, President Chicago Association of Commerce.

Response to Addresses of Welcome: Three-minute responses by representatives of the several states, each with resolution embracing state's most important mining issue.

Tuesday, Nov. 14—10 A. M.

Subject: Safety in Mining Operations.

CARL SCHOLZ, President American Mining Congress, Presiding.

CHARLES S. KEITH, Alternate Chairman, Kansas City, Mo.

Introduction of Resolutions.

Address: The Record of Mine Safety Work, Albert H. Fay, U. S. Bureau of Mines.

Address: State Mine Rescue Methods, Dr. H. H. Stoek, Urbana, Ill.

Address: Safety Work as an Investment, Dr. C. W. Goodale, Butte, Mont.

Address: Responsibilities and the Duties of the Operator, Thomas M. Gann, Knoxville, Tenn.

Address: Of the Miner. David Ross, Springfield, Ill.

Address: Of the Public. Judge W. D. Hoag, Joplin, Mo.

Open discussion under 10-minute rule.

Selection of Committee on Resolutions.

Recess.

Tuesday Evening, Nov. 14—8 P. M.

Annual Members' Meeting for the Election of Directors and the Transaction of Routine Business.

Wednesday, Nov. 15—9 A. M.

Subject: Efficiency in Mining Operations.

HENNEN JENNINGS, Washington, D. C., Presiding.
DR. JAMES E. TALMAGE, Alternate Chairman, Salt Lake City.

Introduction of Resolutions.

Report: Committee on Relations with Federal Trade Commission. Charles M. Moderwell, Chairman, Chicago, Ill.

10 A. M.

Address: Federal Aid to Mining Efficiency. Van H. Manning.

Address: The Federal Trade Commission and the Mining Industry. Hon. E. N. Hurley, Washington, D. C.

Address: Industrial Co-operation Under the Sherman Law. Glen W. Traer, Chicago, Ill.

Address: The Sherman Law and Its Relation to Mining. To be selected.

Address: Efficiency in Ore Treatment. E. P. Mathewson, Anaconda, Mont.

Discussion.

Thursday, Nov. 16—9 A. M.

Subject: "Conservation."

WALTER DOUGLAS, New York City, Presiding.
SAMUEL A. TAYLOR, Alternate Chairman, Pittsburgh, Pa.

10 A. M.

Introduction of Resolutions.

Report: Committee on Forest Relations. Carney Hartley, Denver, Colo., Chairman.

Address: Conservation: Its Purpose, Its Effect, and Who Should Pay for it.

Address: The Accomplishment of Invention and Its Relation to Labor and Capital. Hennen Jennings, Washington, D. C.

Address: Conservation in Mining Through Water Power Development. Charles F. Potter, Los Angeles, Cal.

Address: Waste in the Mining Industry—In Mining—In Distribution and in Use—and the Relation of These Wastes to—The Operator, The Consumer—and the Public. To be selected.

(Continued on next page.)

Address: The State Geologist and Conservation. Dr. A. H. Purdum, Nashville, Tenn.

Address: X-Ray Development. Dr. W. R. Whitney, Schenectady, N. Y.

Address: The New Things in Science. Dr. F. G. Cottrell, San Francisco, Cal.

Thursday Evening, Nov. 16—8 P. M.

Banquet.

Address: Co-operation, the Basis of Safety, Efficiency and Conservation in the Use of the Nation's Mineral Resources. Carl Scholz, Chicago.

Address: Organized Capital and Organized Labor and Their Relation to Efficiency, Conservation, Better Wages, Better Living Conditions, Lawlessness, Strike Disorders and Industrial Freedom. Col. George Pope, Hartford, Conn.

Friday, Nov. 17—9 A. M.

Excursion to Gary, Ind.

GENERAL MEETINGS.

Monday Evening, Nov. 14—8 P. M.

SIDNEY NORMAN, Spokane, Wash., Presiding.

Illustrated Lecture: Mining in the Arctic Regions of Alaska and Siberia. Dr. Henry Maco Payne, New York City.

Illustrated Lecture (Moving): The Cerro Azul Gusher, E. L. Doheny, Security Building, Los Angeles, Cal.

METALLIFEROUS SECTION.

Tuesday, Nov. 14—2 P. M.

IRVING T. SNYDER, Denver, Presiding.

GEORGE E. COLLINS, Alternate Chairman, Denver.

Address: The World's Gold Supply and Its Sufficiency for Business Needs. Dr. Waldermer Lindgren, Boston, Mass.

Address: The Mining Industry. C. A. Tupper, Chicago, Ill.

Address: The Lead and Zinc Resources of the United States. C. E. Siebenthal, U. S. Geological Survey, Washington, D. C.

Address: A Tariff for Revenue as Related to a Compensating Duty on Lead and Zinc Ores. Otto Ruhl, Joplin, Mo.

Address: The Copper Resources of the United States. Walter Harvey Weed, New York City.

Wednesday, Nov. 15—2 P. M.

HON. ALBERT JOHNSON, Hoquiam, Wash., Presiding.

W. W. RISON, Alternate Chairman, Albuquerque, N. M.

Topic: Mine Manufacturing the Best Industry of the Rocky Mountain West. John Hays Hammond, New York City.

Address: How to Protect the Small Investor in Metalliferous Mines. Hon. W. R. Allen, Butte, Mont.

Address: Smelter Contracts and Market Quotations. R. M. Henderson, Breckenridge, Colo.

Address: Copper in Its Relation to Preparedness and Industrial Efficiency. To be selected.

Address: The Marketing of Zinc Ores. W. B. Shackelford, Webb City, Mo.

Address: Oil Flotation. Dorsey A. Lyon, Salt Lake City.

Address: Co-operation in the Lead and Zinc Industry.

Open Discussion under 5-minute rule.

Thursday, Nov. 16—2 P. M.

D. W. BRUNTON, Denver, Presiding.

Report: Committee on Revision of Mineral Land Laws. E. B. Kirby, New York, Chairman.

Address: The Foster Bill. Dr. M. D. Foster, Chairman, House Committee on Mines and Mining.

Address: The Revision of Mining Laws. Hon. Chas. S. Thomas, U. S. Senator from Colorado, and Frank L. Peckham, Washington, D. C.

General Discussion.

Address: The Rate Metals. Dr. R. B. Moore, Denver, Colo.

Address: The Prospector and the Apex Law. Theo. F. Van Wagenen, Denver, Colo.

Address: Workmen's Compensation in the Metalliferous Mining Industry. Hon. Thomas Kearns, Salt Lake City, Utah.

Address: Electrolytic Separation. Frederick Laist, Anaconda, Mont.

OIL SECTION.

Tuesday, Nov. 14—2 P. M.

RALPH ARNOLD, New York City, Presiding.

Address: The Oil Resources of the United States. W. A. Williams, U. S. Bureau of Mines.

Address: The Authority of States to Tax Production from Indian Lands. Hon. J. G. Gamble, Asst. Atty. C. R. I. & P. Ry., Des Moines, Iowa.

Address: Oil Land Withdrawals. Judge George H. Patrick, Washington, D. C.

Address: The Relation of the Federal Government to Western Oil Production. W. R. Wheeler, Washington, D. C.

(Continued on next page.)

Address: The Federal Government and the California Oil Claimants. Hon. Jas. D. Phelan, Senator California.

Discussion: Led by Thomas A. O'Donnell, Los Angeles, Calif.

OIL AND GAS SECTION.

Wednesday, Nov. 15—2 P. M.

DR. NORMAN BRIDGE, Los Angeles, Cal., Presiding.

Address: Geology in Its Relation to the Oil Industry. C. C. McDowell, Pittsburgh, Pa.

Address: The Standardization of Oil Testing Methods. W. H. Fehsenfeld, Baltimore, Md.

Address: The Future of the Dye Industry Through the Use of Petroleum. Dr. Walter F. Rittman, Empire building, Pittsburgh.

Address: Practical Phases of the Standard Oil Dissolution, and the Necessity of Combinations Among Independent Producers to Meet Unfair Competition. R. N. Welch.

Address: Federal Co-operation with the Oil Industry. H. G. James, Kansas City, Mo.

Thursday, Nov. 16—2 P. M.

S. Y. RAMAGE, Oil City, Pa., Presiding.

Address: The World's Oil Supply. Ralph Arnold, New York City.

Address: Naval Oil Reserves as a Necessity to National Preparedness. To be selected.

Address: The Future of the Natural Gas Industry. Judge Thomas J. Flannelly, Independence, Kas.

Address: The Relation of the Federal Government to Scientific Research in the Oil and Gas Industry. To be supplied.

Address: Modern Oil Storage. To be supplied. Discussion led by Alf. G. Heggem, Tulsa, Okla.

Address: The Chemical Possibilities of Petroleum. Dr. David T. Day, Washington, D. C.

COAL SECTION.

Tuesday, Nov. 14—2 P. M.

C. M. MODERWELL, Chicago, Presiding.

Report: Committee on Uniform Cost Accounting System. S. A. Taylor, Pittsburgh, Chairman.

Address: Co-operation in the Marketing of Coal. Ralph Crews, Chicago, Ill.

Discussion under 10-minute rule.

C. P. White, Cleveland, Ohio; C. G. Hall, Terre Haute, Ind.; R. A. Hord, Lexington, Ky.; W. P. DeArmit, Pittsburgh; G. H. Barker, Columbus, Ohio; W. H. Huff, Denver, Colo.; H. N. Taylor, Kansas City, Mo.; W. J. Spencer, Brereton, Ill.; Jas. E. McCoy,

Knoxville, Tenn.; T. L. Lewis, Charleston, W. Va.; W. W. Bridges, Drakesboro, Ky.; W. H. Cunningham, Ashland, Ky.

Open Discussion under 5-minute rule.

Report: Committee on Workmen's Compensation. T. L. Lewis, Charleston, W. Va., Chairman.

Address: The Cost of Coal. George Otis Smith and C. E. Leshner, U. S. Geological Survey.

Address: New Ideas in the Preparation of Eastern Coal. Warren Roberts, Chicago, Ill.

Address: The Disadvantages of Widely Fluctuating Coal Prices. Hugh Shirkie, Terre Haute, Ind.; D. J. Jordan, Oklahoma City, Okla., and John Laing, Charleston, W. Va.

Wednesday, Nov. 15—2 P. M.

DR. I. C. WHITE, Morgantown, W. Va., Presiding.

Address: The Colorado Industrial Commission. Wayne Williams, Denver, Colo.

Address: Co-operation in the Coal Industry. H. E. Willard, Cleveland, Ohio.

Address: The Duties of Mine Inspectors. J. W. Paul, Pittsburgh, Pa.

Address: The Closed Shop and the Check-off as Related to Efficiency in Mining Operations. Dorset Carter, Oklahoma City, Okla.

Address: What Comes of the Benefits of Production Efficiency? George H. Cushing, Chicago, Ill.

Address: The Influence of Inter-district Competition on Economy in Southwestern Coal Production. J. G. Puterbaugh, McAlester, Okla., and Harry N. Taylor, Kansas City, Mo.

Address: Cohesion Among Coal Operators. Thomas T. Brewster, St. Louis, Mo.

Address: The Experience of Anthracite Operators in Storing Coal to Equalize Production. E. W. Parker, Wilkes Barre, Pa.

Thursday, Nov. 16—2 P. M.

J. C. KOLSEM, Terre Haute, Ind., Presiding.

Address: Coal and Its By-Products. Alfred M. Ogle, Terre Haute, Ind.

Address: Two Years' Experience in the World's Coal Markets and Its Lesson. F. S. Landstreet, New York City.

Discussion.

After the Association, What? W. S. Bogle, Chicago, Ill.

Unequal Distribution of Bituminous Coal and Its Cost to Operator, Retailer and Consumer. K. U. Maguire, Louisville, Ky.

Wasteful Methods of Coal Distribution. Chas. L. Dering, Chicago, Ill.

Difficulties I Have Met in Coal Litigation and the Remedies. R. W. Ropiequet, Belleville, Ill.

The Future of Coal Export Industry and the Necessities for Its Success. J. A. Renahan, New York City.

Who's Who in the Jos. A. Holmes Safety Association

In a previous issue we referred to the organization which had its origin in the endeavor to give proper recognition to one of the greatest public servants that the United States ever saw and of whom President Wilson has said in introducing this Association to the public:

In the death of Dr. Jos. A. Holmes the country has lost a public servant of unusual character and of singular devotion to duty. We are often called upon to note the career of some public benefactor, but we do not often enough note the services of the devoted men who, with little compensation and little public fame, seek to advance the interest of their fellow-countrymen through services of the departments of the Federal Government at Washington. Dr. Holmes was one of the most distinguished and most serviceable of these. He devoted his whole time and thought to turning science to human and generous use.

Inasmuch as the Dr. Holmes Safety Association is altogether remarkable in its purpose and in the national spread of its organization, it is interesting to note who the men actually are who have been taken from a membership of 50,000 or 60,000 men to do the actual work of this association. It is made up of the following representatives of the national societies taken in alphabetical order of the societies which they represent:

Dr. L. O. Howard is the permanent secretary of the American Association for the Advancement of Science. Probably there is no man in the United States whose sympathetic personality as well as his national relationship with scientific men, who is so thoroughly acquainted with what can be done nationally in general movements of this sort. It is unnecessary to say that he was one of Dr. Holmes' personal associates, especially in the Cosmos club in Washington.

Dr. Charles Baskerville, representative of the American Chemical Society, is professor of chemistry in the University of New York. For many years he has been professor of chemistry in the University of North Carolina, and has been associated with the work of Dr. Holmes in his native state.

Dr. F. G. Cottrell, representing the American Electro-Chemical Society, has become nationally known as a developer of the Cottrell process for condensing flue dust. He is even better known as an altruist who has dedicated the great financial returns for which his patent are capable, to the formation of a company for the development of technologic processes generally.

A. E. Holder is one of the chief organizers and administrators of the American Federation of Labor, and naturally brings to this association a thorough understanding of the problems which confront the miner and other laborers in live industries. He knows their weaknesses, their tendency to recklessness, and he best knows how these characteristics can be fought and the miner developed.

P. S. Ridsdale, representing the American Forestry Association, will be closely associated with Mr. Holder in developing safety among the ax-men and other laborers in the lumber trade.

John H. Finney, acting for the American Institute of Electrical Engineers, has become a national character in his efforts to develop sane legislation concerning conservation of the country's reserves, especially water powers in the southern states.

Hennen Jennings has been selected as representative of

the American Institute of Mining Engineers because of the fact that he is spending all of his time at present in applying a long life of experiences in mining engineering to the betterment of mining conditions. He is taking to heart the example and the experiences of Eckley B. Coxe and E. W. Parker and other men who have spent their greatest energy in developing mining.

Dr. David T. Day, of the Bureau of Mines, represents the American Mining Congress. He is exceptionally well known in the mining fraternity, because of his public service as the organizer of the reports on the mineral resources of the United States in the U. S. Geological Survey. In publishing some 20 annual reports of this character, Dr. Day has been associated with mining men of all kinds and has an unusually large acquaintance.

Maj. Robert U. Patterson represents the American Red Cross Society. Dr. Holmes allied himself with the American Red Cross as with every other movement associated with rescue work or mine betterment, and the society has entered energetically into this new nation-wide movement.

Dr. A. W. Gibbs of the American Society of Testing Materials is perhaps one of the best known members of that society.

Dr. John A. Brashear of Allegheny, Pa., president of the American Society of Mechanical Engineers, has consented to represent that body. As everybody knows, Dr. Brashear is more responsible than anyone else for the team work which characterizes scientific technical work in Pittsburgh. When, last summer, the governor of Pennsylvania selected him as the greatest citizen of Pennsylvania, it was giving a new kind of recognition to a man known all over the world for his scientific attainments. On Dr. Brashear's last birthday over 1000 scientific men and other friends gathered in Pittsburgh to do him honor, and the demonstration included a parade of 40 different scientific societies of which he is a member. Perhaps he has become nationally better known by the name by which Pittsburgh has always known him, "Uncle John." By the article appearing in the American Magazine last summer his alternate and Washington representative in this work is Gen. W. H. Bixby, a man whose constant work in the betterment of labor conditions is well known.

Van H. Manning, director, represents the Federal Bureau of Mines. Not even Dr. Holmes could be said to have any bigger heart than Manning. This could not be better shown than by his loyalty to his former chief and the steadfast way in which he has continued to develop his projects, and his big heart and loyalty go further. The mining fraternity is already recognizing that he is their greatest national friend.

Dr. Jos. Hyde Pratt, representing the Geological Society of America, was a fellow associate of Dr. Holmes and succeeded him as state geologist of North Carolina.

Eugene McAuliffe represents the International Railway Fuel Association. In certain ways Mr. McAuliffe has entered into the work of this association with a keen sympathy for the purpose and understanding of the problem which separate him out from all the others.

J. W. Paul of the Mine Inspectors' Institute was long associated with Dr. Holmes in the Bureau of Mines and is in perhaps closest touch with rescue work among the coal mine operators.

Geo. S. Rice represents the Mining and Metallurgical Society of America. Mr. Rice was the first to propose a memorial for Dr. Holmes, and took up, as temporary secretary, all of the preliminary work and brought it to the stage of an organization. He is better acquainted with the conditions of coal mining than any other man in America from the standpoint of mine betterment.

Dr. David White of the National Academy of Sciences is

THE LATE DR. JOSEPH A. HOLMES.

chief geologist for that organization and represents most adequately the personal friends of Dr. Holmes in Washington.

H. M. Wilson represents the National Safety Council, an organization which will always stand in close touch with the new organization, inasmuch as the chief work of the Safety Council is a related one of developing new ideas of mining safety.

Dr. Chas. D. Walcott of the Smithsonian Institution ranks with the largest organizers of the American states, a capacity which he developed as director of the U. S. Geological Survey.

M. E. Wadsworth and his alternate, O. P. Hood, chief mechanical engineer of the Bureau of Mines, will represent the Society for the Promotion of Engineering Education.

William Green, president of the United Mine Workers of America, has associated himself with this project from its beginning and will bring to it the sympathy of the entire mining workers' fraternity.

Dr. Jos. D. Cannon of the Western Federation of Mine Workers will bring the sympathy and co-operation of all the mine workers of the United States.

Dr. George Otis Smith, director of the U. S. Geological Survey, represents that organization, in which Dr. Holmes first developed the project of a national Bureau of Mines through the Technologic Branch of the Survey which he organized after the World's Fair of St. Louis.

The morning after Dr. J. A. Holmes was appointed by the president, director of the Federal Bureau of Mines, it is said that his desk contained the largest pile of telegrams of congratulation ever sent to a government official. As we know, Dr. Holmes threw into this work a whirlwind of energy which brought into order a universally organized structure—the Bureau of Mines—in so short a time as to make the mining world fairly gasp with surprise.

Hardly had the world felt that a great work was in progress for the benefit of mining, when it was shocked by the death of Dr. Holmes—the necessary result of his putting into the task more energy than any one man could continually produce. As Day put it, "He gave his life to the mining industry."

It is impossible to conceive that such a life would go out without some sufficiently great memorial to his work, and it has been a matter of some surprise that thus far nothing has been forthcoming. It now is obvious that this delay has been fitting and appropriate in the effort to develop adequate recognition of this great public servant. The movement was begun by the American Institute of Mining Engineers, who appointed a committee to act with other national societies in arranging a memorial.

Promptly at its annual meeting the American Mining Congress appointed a similar committee. This met and felt justified in asking 20 other national societies affiliated with mining interests, and of most of which Dr. Holmes was a national member, to join in organizing a proper memorial. They formed the Jos. A. Holmes Safety Association, consisting of representatives of these national societies.

Considering the nature of the memorial, it was evident at the outset that an ordinary memorial, monument or tablet was inconsistent to the character of the man and his work. The feeling was unanimous that a mere statement in the form of what Dr. Holmes had accomplished, or what he aimed to ac-

complish, was inadequate. Fortunately, Dr. Holmes was single-minded in his idea of what he hoped to accomplish. It was simply the betterment of mining conditions in the United States, especially the condition of miners themselves and of like workmen in a live industry where the products of the mine are manufactured in useful commodities. It seemed easy to associate the whole idea with "Safety-First," an expression which did not originate with Dr. Holmes, but which he was first to apply, nationally. The association resolved, therefore, to carry forward the work of developing safety in mines and mining industries by such means as are not already taken care of by other enterprises. For efficiency and management, the following executive committee has been selected and the work will go forward rapidly in their hands:

President, Van H. Manning, director Bureau of Mines.

Vice-President, Chas. D. Walcott, secretary, Smithsonian Institution.

Second Vice-President, Samuel Gompers, president American Federation of Labor.

Hennen Jennings, American Institute of Mining Engineers.

Dr. John A. Brashear, president American Society of Mechanical Engineers.

The first object of the association will be to provide awards for ideas which will increase safety in mining, and again to provide a medal for each man who contributes to the safety of another man at the risk of his own safety, which is a good definition of a hero.

Mining Issues Pending Before Congress.

Discussing the various issues now pending before Congress, Secretary Callbreath of the American Mining Congress, says:

"The next session of Congress will have under consideration the Foster bill for revision of the mineral land laws of the west. It will be recalled that a bill for a commission to investigate conditions through public hearings in the western mining centers and make recommendations to Congress was introduced by Senator Smoot and passed the Senate, but failed to receive the approval of the House committee on mines and mining. In its stead Dr. Foster, chairman of the committee, introduced a bill intended to meet the requirements without the preliminary work of a commission. This bill was severely criticized by the west and the mining journals. A thorough discussion of the subject will take place at the Chicago convention. Dr. Foster himself will lead the discussion and defend the plan he proposes. The discussion will be lively if the critics of his bill meet him on the floor. A plan for future action will probably be outlined, and a campaign begun to bring about the practical legislation desired.

What the Mining Companies are Doing

International Nickel Co.

International Nickel Co. made profits of \$6,344,246 in the 6 months ended Sept. 30 while surplus after dividends amounted to \$3,566,793. From the semi-annual statement just issued it becomes apparent that the third quarter of the year practically duplicated the June 30 quarter, in which profits were \$3,959,135.

In both periods earnings were of record proportions. Cash at the end of September was down to \$2,081,110, against \$4,137,633 on June 30 but on the later date certificates of deposits had grown to \$4,280,000 from \$2,030,000 at mid-year.

The consolidated profit and loss statement for the 6 months ended Sept. 30, compared with the official June 30 quarter and the estimated Sept. 30 operations, follows:

	Six mos. Sept. 30.	June 30 quarter.	Estimated Sept. 30 quarter.
Earnings	\$7,775,145	\$3,959,135	\$3,816,010
Other income	137,628	66,262	71,366
Total income	\$7,912,773	\$4,025,396	\$3,887,377
Admin. and general expense...	563,896	222,422	341,474
Net income	\$7,348,876	\$3,802,974	\$3,545,902
Depreciation and mineral ex- haustion	1,004,630	497,409	507,230
Profits	\$6,344,246	\$3,305,574	\$3,038,672
Dividends	2,777,454	133,689	2,643,765
Balance	\$3,566,793	\$3,171,885	\$ 384,907

The balance sheet of the International Nickel Co. as of Sept. 30 compares:

	1916.	1915.
Assets.		
Property	\$44,191,831	\$43,649,163
Investments	2,003,396	57,760
Inventories	4,773,758	3,170,143
Accounts receivable	2,045,156	1,491,197
Loans on call	515,000	1,000,000
Certificates of deposit.....	4,289,000	5,500,000
Cash	2,081,110	1,907,888
Total	\$50,892,251	\$56,976,152
Liabilities.		
Preferred stock	\$ 8,912,600	\$ 8,912,600
Common stock	41,834,600	38,031,500
Accounts payable	1,951,255	1,003,458
Preferred dividend	133,680	133,689
Common dividend	3,803,150
Account and insurance funds.....	199,119	180,813
Previous surplus	3,294,195
Profit and loss surplus.....	3,566,703	4,910,941
Total	\$50,892,251	\$56,976,152

Shattuck-Arizona Ore.

The Shattuck-Arizona Copper Co.'s report for the quarter ended Sept. 30 compares with the previous quarters as follows:

	Sept. 30.	June 30.	Inc.
Gross earnings	\$1,275,890	\$1,207,780	\$68,110
Expense and taxes.....	534,692	518,164	16,528
Net earnings	\$ 741,198	\$ 689,616	\$51,582

This makes total net earnings for the 9 months approximately \$3,212,000, or at the rate of \$7.70 a share for the year. Net of \$741,198 for third quarter is at the rate of \$8.47 a share for the year. In the 12 months Shattuck should show earnings of at least \$8 a share.

Copper production amounted to 4,663,466 lbs. at a cost of 9.20 cts. a pound, compared with a production of 4,169,873 lbs. in the previous quarter at a cost of 10.44 cts. a pound. There were also recovered 1243 ozs. of gold, 79,995 ozs. of silver and 661,034 lbs. of lead.

Refinery delivered 4,312,049 lbs. of refined copper. Including unsold copper at 25 cts., average sales price of third quarter's production was 25.05 cts. a pound against an average for previous quarter of 26.85 cts.

Tennessee Copper & Chemical Co.

The plans for rehabilitating the Tennessee Copper Co. call for two active companies, one of which—the newly organized Tennessee Copper & Chemical Co.—will act as a holding and banking company. The outstanding bonds of Tennessee Copper Co. will remain undisturbed.

Something new for a copper company will be the proposed 5 years' voting trust. It will also be the third copper company to issue stock without par value, the pioneers being Kennecott and Cerro de Pasco.

The new interests in charge were with the company in its early days and during the construction of the original sulphuric acid plant. It is expected that the company ultimately will sell all of its assets—(mining properties, smelter and sulphuric acid plant) to the Tennessee Copper & Chemical Co.

The company will net \$2,800,000 from the sale of 200,000 shares of stock which go to the bankers at \$14 per share, to underwriters at \$15 and to stockholders at \$16. Pressing needs approximate \$2,750,000 comprised principally of: Advances by Russia, \$1,140,000; due banks and others, \$1,500,000; total, \$2,640,000.

Miscellaneous.

C. F. Kelley, managing director and vice-president of the Anaconda Co., states that the new zinc plant at Great Falls, is proving a great success. Two of the five units now in operation are turning out 60 tons of zinc per day, which is 10 tons more than the theoretical capacity. Owing to the delay in the delivery of certain heavy machinery other units will not be in operation until the first of the year. Work has just been started on a \$100,000 bag house which will be completed the first of the year and will contain 1440 bags through which will pass fumes from the reverberating furnace, the bags collecting the lead now wasted.

Shortage of labor, particularly trammers, continues to handicap the Lake Superior copper companies. Wolverine was able to ship during September but 27,455 tons of rock; in July the total milled was 29,275 tons. The copper yield amounted to but 470,190 lbs., which was the lowest monthly output since January. The yield per ton was 17.12 lbs. President Stanton has gone on record with the prediction that Wolverine has at least another 10 years to live. The immediate problem is that of getting the best results from the rock remaining. As no stopping will be necessary, the copper to come from the lower Wolverine workings should be secured at a low cost.

Operations at the Shattuck-Arizona in September resulted in a production of 1,566,446 lbs. of copper from 14,486 tons of ore. There was also obtained 26,928 ozs. of silver and 419 ozs. gold. In addition 805 tons of lead ore were shipped to the El Paso smelter for treatment. The net cost of producing copper after crediting income from subsidiary metals was 9 cts. a pound. The net profit for the month totaled \$260,028, which is at the rate of \$8.92 a share per annum. During the 9 months ended Sept. 30 Shattuck produced 13,543,030 pounds of copper; 240,040 ozs. of silver; 3828 ozs. of gold, and 6273 tons of lead ore. The cost of copper during the above period was 8.42 cts. a pound and the company earned \$2,213,994, equivalent to \$8.43 a share per annum.

According to B. H. Dosenbach, who installed the flotation process at the Boston & Corbin property, the results obtained are attracting considerable attention. The flotation treats all tailings made in the concentration portion of the mill, which necessarily gives the unit a very lean tonnage to work on. With heads of about ¾% copper it was expected that a 9% copper concentrate would be made. The first half of October the actual result was 13.4% copper and 9.9 ozs. in silver. The tailings from the unit contain less than 0.2% copper. Changes in the mill have greatly increased the tonnage treated. It has handled 100 tons daily during October and on one day over 130 tons. The average grade of concentrates has been steadily improved, and it is now running over 5¼%. There is good reason to expect that both tonnage and grade can be further improved. There is, in fact, prospect that, barring unforeseen developments, Boston & Corbin in October will show a profit from operations.

Mines' Dividend Statistics Educate Public to Importance of Mining.

At the Arizona meeting of the American Mining Congress the late Dr. Holmes emphasized that one of the most important lessons that should be learned thoroughly in order that the people of the United States may understand the importance of mining industry, was to do as the railroad companies of the country are doing—educating public sentiment to what that great industry is.

What more favorable publicity could be given the mining industry than is now afforded by the dependable dividend statistics as published in the Mining and Engineering World. The greatness of the industry and the wonderful productiveness of its mines are clearly shown by the unusually large dividends that have accrued to holders of mining stocks in the past and are continuing at an unprecedented rate.

It is to be regretted that statistics of earlier dividend paying companies are not available at the present writing for with these added to the disbursements of present-day dividend payers a total would be reached of startling size.

The wonderful earning powers of American mines and works can best be illustrated by referring to the disbursements made by 167 companies during the 10 months of 1916. These companies, between Jan. 1, 1916, and Oct. 31, 1916, divided among shareholders the princely sum of \$184,830,127. If the dividend payments of the securities-holding corporations were to be included (and a large proportion could be rightfully included), the year's total would reach \$223,433,208, a wonderful and convincing argument that mining, as now carried on, is one of the principal reasons for our present standing at the head of the world's great industrial centers.

That these companies not only enjoyed a remarkable prosperity during the past 10 months, but in previous years we are able to show by reports made to Mining and Engineering World, that these companies paid dividends amounting to \$1,067,277,064, which, with the dividends paid in 1916 makes a total of \$1,252,107,191. This is a return of better than 133% on the combined issued capital of the companies. When it is considered that a large number of these companies did not pay a dividend previous to 1915 or 1916, this is a remarkable record and one, we believe, not duplicated by any other industry.

While October disbursements were not as large as during the previous month they were considerably larger than in any other October in the history of American mining industry. With 60 companies participating, dividends were paid to shareholders during the month totaling \$16,663,385. This does not include the \$630,000 disbursed by the holding companies. The copper companies contributed \$7,517,580 of this, the gold-silver-lead-zinc companies \$8,154,447 and the metallurgical companies \$991,358.

Of the 167 companies participating in the 1916

disbursements 42 operate copper properties, all but two in the United States, and these divided among shareholders \$88,280,814. In previous years these companies paid dividends amounting to \$571,530,726, making their total to date \$659,811,540. This is a return on the combined issued capital of 186%.

One hundred nineteen properties, classified as gold-silver-lead-zinc producers, paid dividends during the 10 months of 1916 amounting to \$77,149,398. Added to dividends paid in previous years brings their total to \$380,088,724, on the combined issued capital of \$309,979,039, a return of practically 124%.

Of the 119 companies mentioned above 91 are operated in the United States and they have to their credit in 1916 dividend payments of \$64,530,768. Added to the dividends paid previously brings their total to \$294,657,558, a return of approximately 150% on the \$197,644,778 outstanding.

Twenty-three of the above 167 companies operate properties in Canada and they contributed to the 1916, \$9,210,621, making their total to date \$69,522,318. This is a return of nearly 75% on the outstanding share capital and is a splendid record considering the comparatively few years of operation.

But three Mexican companies report as having paid dividends in 1916, these paying \$1,108,009. To date these companies have disbursed \$8,858,848.

Six metallurgical companies, looking to their profits largely from the treatment of ores for other companies had a very prosperous 10-months' period, for they disbursed among shareholders \$19,399,915. Added to previous disbursements these companies have paid dividends totaling \$212,206,927. This is a return of approximately 80% on the \$273,003,040 outstanding share capital.

Eight securities-holding corporations, mentioned above, divided among shareholders during the 10 months of 1916, no less than \$19,399,915. Since incorporation disbursements total \$156,054,205.

In the following table is given a list of companies paying dividends in October, the date of payment, amount per share and amount paid:

	October.	Per share.	Amount paid.
Ahmeek, Mich.	10	\$4.00	\$800,000
Allouez, Mich.	4	2.50	250,000

Science Expanding Copper Output.

In considering the future of the copper metal situation and its relation to investments, a Copper Country correspondent writes that there is one point to which very little attention has been directed, yet it is of greatest importance relative to the world's output of the metal. At present the output of copper is the largest in history, due to the fact that all regular producing mines are operating to the limit of capacity and many smaller mines are working now that could not operate profitably when the price of the metal is at its average.

When the European war ends and the sensational demands for war munitions are a thing of the past, there will be a continuance of an unusual production, even if the high cost properties are compelled by the drop in price to shut down. The larger producing interests have already accomplished, by improvements in treatment of their copper rock, or copper ores, a big stride forward toward a large production. Anaconda, for instance, by utilizing the flotation process, has brought its savings of copper from 76% up to 92%. Some of the porphyries are doing the same thing by the same process. The operation of regrinders and the leaching process at the Calumet & Hecla will, when the system is completed, cut the losses in the copper sands from this mine down to such a small figure that Calumet & Hecla can get 95% of all the copper out of the rock, whereas a 50% loss was nothing to bother about in the early days.

These improvements in concentration make for a larger output of copper metal from the same amount of mine rock taken out. They are, of course, offset to an extent in most properties, by a lower grade of rock mined, but they make possible the successful treatment of a lower grade. They are facts worthy of consideration in connection with the discussions of metal prices following the conclusion of the war in Europe.

PERSONAL.

J. Parke Channing of New York is visiting various western sections.

George Nordquist of Chicago recently inspected mining properties in Utah.

J. W. McBride of Spokane has been inspecting mining properties in British Columbia.

Dr. L. D. Ricketts recently inspected a copper property in the vicinity of Jerome, Ariz.

Charles A. Peet, consulting engineer, recently examined the Goldstrike-Virginia property, Utah.

George O. Bradley of San Francisco is looking over the new work being done at the Utah Copper property.

W. H. North of the Standard Silver-Lead Mining Co. in British Columbia has been in Wallace, Idaho, recently.

R. E. Gardner, mining engineer, recently inspected a mining property in Barton Gulch, Madison county, Montana.

Richard Lockey of Helena, Mont., has been in the Coeur d'Alene region of Idaho, looking after mining interests.

J. J. Morrison, superintendent of construction for the Empire Zinc Co., has returned to Canyon City, Colo., from New York City.

L. P. Barrett, geologist for the Michigan Board of Geological Survey has recently been at Houghton, Mich., on business for the state.

C. W. Whiteley, general manager in the northwest for the American Smelting & Refining Co., is conferring with company officials in the east.

Hugh H. Tarbet will superintend operations at the property of the Fort Schellbourne Mining & Milling Co. in White Pine county, Nevada.

W. Parsons Todd, of New York, vice-president of the Quincy and a director of the Adventure, is in the Michigan copper country on business connected with the mines.

Frederick Burbidge, general manager of the Federal Mining & Smelting Co., has returned to the Salt Lake office of the company, after a 2 weeks' visit to the property in Idaho.

Chester Ellsworth of Virginia City, Nev., is in Prescott, Ariz., from which place he will direct investigations of mining properties in the vicinity for San Francisco-Tonopah interests.

Prof. Michiga Siroaka of the Higher Technical schools of Osaka, Japan, is at Houghton, Mich., for the purpose of studying the mines and smelters of the Lake Superior copper district.

W. R. Bolley, superintendent of the White Pine Extension, has been made assistant superintendent of the Wolverine. Mr. Bolley will reside at Kearsarge, the residence location of the latter.

William Corkill, who has been in charge of the underground work at the property of the Volunteer Ore Co., on the Cascade range, Michigan, will take charge of the development work of the North Butte Co.

H. J. Stander, flotation engineer with the Yaryan Rosin & Turpentine Co., Brunswick, Ga., and author of "The Flotation Process," just published by the Mining World Co., was in Chicago last week on his way to Ontario, where he

will superintend experimental flotation work for the Mond Nickel Co. at Sudbury.

OBITUARY.

Alexander McKinnon, a pioneer of Iron county, Michigan, and the founder of Iron River, Mich., died Oct. 17, after a 2 weeks' illness. He was born in Mull, Argyllshire, Scotland, in 1842, and crossed the ocean when an infant with his parents. The latter settled on a farm on Owen Sound, Canada, where he attended school when opportunity offered, learned to handle tools and assisted his father in building boats to ply the Great Lakes. After mastering the carpenter's trade at the age of 17 years he struck out into the world to make his fortune and located at Marquette, just at the time the upper peninsula was becoming known as a prospective mining region. After following the carpenter's trade a while he learned to burn charcoal, then an important industry. In 1878, with his brother, Daniel McKinnon, he walked from Quinnesec to Iron River, the two carrying their tent and supplies on their back the whole distance of 50 miles and pitched their camp, which has since become the prosperous village of Iron River. The two filed claims on different mines and tracts of land and cleared 4 acres in 1882, built a shanty and planted potatoes, the first attempt at farming in this part of the state. Early in the same spring Mr. McKinnon and his brother platted the town of Iron River and the same year opened the Beta mine. He had large interests in various mining properties at the time of his death.

SCHOOLS AND SOCIETIES.

Haileybury School of Mines.—The new mining and millinery laboratory of the Haileybury School of Mines is nearing completion and the school is now getting its machinery and equipment. The laboratory will comprise a complete small size concentrator, a cyanide mill, flotation plant, assay office, blacksmith shop, and carpenter shop, and will contain most of the machines met with in these lines. The school has the co-operation of the mines of the Haileybury (Ont.) district and of the manufacturers of mining machinery.

Rocky Mountain Club.—The Rocky Mountain Club will receive election returns by Western Union service on Tuesday, Nov. 7, at the clubroom. The first of a series of their famous "No Limit" beefsteak dinners to be given during the season will be served at the clubrooms on the same evening at 7 o'clock. The Rocky Mountain Club, of which John Hays Hammond is the first and only president, will celebrate the tenth anniversary of its birth on Tuesday, Jan. 9, 1917. This promises to be a big night for western men, and those concerned in western development, and celebrations will take place in the large cities in the west on the same evening.

Colorado Metal Mining Association.—The annual meeting of the Colorado Metal Mining Association has been called by the executive committee of the association for Jan. 3, 4 and 5. Mine operators, employes and all interested in mining, will be invited to attend the meeting, at which a number of important questions will be discussed. A representative of the Department of the Interior at Washington will be present to discuss with the mining men their protests against the government's conservation policies and withdrawals of public lands. Other questions to be discussed are "The Proposed Repeal of the Present Law for the Taxation of Producing Mines," "Proposed Regulation of Smelters by the State Public Utilities Commission," "Changes in Laws Regarding Compensation and Industrial Insurance," "Tariff Laws" and "The Proposed New Federal Mining Law."

Late News From the World's Mining Camps

Editorial and Special Correspondence.

ALASKA.

That part of central Alaska lying between the lower Koyukuk river and the Yukon was until recently but little known. In 1913 it was explored by H. M. Eakin, and his results are presented in a report entitled "The Yukon-Koyukuk region," recently issued by the Geological Survey as Bulletin 631. The region is essentially a rolling upland above which rise some higher mountain masses reaching altitudes of 5000 to 6000 ft. This upland is broken by broad valleys and lowlands. The mountain slopes are clothed with spruce trees up to altitudes of 2000 ft. Spruce and birch also cover the lowlands. Above timber line the vegetation is chiefly moss. The timbered areas, notably in the lowlands, are broken by meadows covered with a luxuriant growth of grass. Moose, caribou, and bear still roam over much of this region, which is seldom visited by white men. No important mineral resources have been found in the Yukon-Koyukuk region, but many of the stream gravels carry some fine colors of gold. This gold seems to have been derived from the contact zones of granitic intrusive rocks, which are abundant in the region. That some of these deposits are of commercial importance is shown by the fact that the placers of the Indian river district, which lie in the Yukon-Koyukuk region, have for several years been mined on a small scale. It is not improbable that other commercial placers may be found in the region, but the prospecting thus far done does not indicate the presence of any very rich deposits.

Valdez.

On the lowest or 4th level a strike has been made in the mines of the Alaska Mines Corporation. It was encountered while mining a tunnel and is reported as a 6-ft. vein of high-grade chalcopryrite. The extent of the deposit is not yet known. This find shows that the development so far done has demonstrated that the vein not only carries the ore marked on surface, but that the vein is persistent.

Anchorage.

A recent cleanup of a 13-day run at the Martin mine in the Willow Creek district had a total value of \$26,000. Martin reports that they are just getting into good ore and that he will run the mill just as long as the weather permits. He will keep a force of rock miners in the mine through the winter and will possibly put in electric power next spring and run the year around. He expects to commence extensive development on other quartz property in the district next spring.

Brooks.

There is plenty of water now in this district and considerable freight is being brought in. Among some of the encouraging things is the discovery by N. A. Brown and George Kilmar on Lucky gulch, at the head of Livengood creek, which appears to be an old lake bottom. The ground is 105 ft. deep. Pay is as good as that found on any of the claims toward the upper end of the creek. The operators are now crosscutting the claim to determine the extent of the pay.

Juneau.

According to A. S. LeNeau things are not encouraging for the small operator in the Lituya Bay country. There is gold in the country, he states, and plenty, but to operate profitably the ground must be worked on a large scale. In describing the country, he says: "The sands are spotted. A miner may strike a spot and take out a couple of ounces and then the sands will become barren. There is no lead and no gravel to work. I do not think there will be a miner in the

district this winter. Everyone signified his intention of coming out."

ARIZONA.

Globe.

An experimental leaching plant is now being constructed at Inspiration for determining a method which will extract carbonate and silicate values now going to waste with the tailings. The 6th level drift from the inclined shaft to the Joe Bush body will soon have reached its objective, so that active development work on the lower section of this ore body will be possible.

The 3-compartment working shaft at the North Dominion, started some days ago, is progressing, and is now working two shifts. The shaft is being sunk at the intersection of the limestone and quartzite ledges. Experts claim that the main vein should be cut at 300 ft.

The 2-compartment shaft of Miami Con. has been started. A crew of 30 men will proceed to develop the company's commercial ore body with a view to making shipments at once. Nineteen men have been engaged in getting out commercial ore for more than a month, but the operations will be extended immediately and a much larger crew employed. Orders have been placed with the Star Drill Machine Co., Akron, Ohio, for two large churn drills.

Bisbee.

In the monthly report by Supt. Houle of the Shattuck-Arizona it is stated that between the 200 and 100 levels, a large body of oxide ore assaying 6½% has been opened. It has been exposed for 130 ft. and continues to make to the south and west. The same ore was encountered in crosscuts 3 and 5 on the 100 level, and we expect to encounter it with crosscut No. 6 on the 100 level. On the 200 level south of the shaft, on the Iron Prince claim, we have opened an important shoot of high-grade copper and lead ore in crosscuts 11 and 12. The lead is found in crosscut 11 on the foot wall of the copper ore and will average 14% and \$6 in gold and silver. The copper on the hanging wall has been exposed for a width of 11 ft. and a length of 31 ft. The ore will average 5% copper and \$2 gold and silver. Promising new territory is being developed in crosscuts 72, 75 and 77 on the 500 level. This is entirely new territory. We are prospecting the same territory from the 600 level in crosscuts 66 and 67. The developments in crosscut 66 are especially encouraging. On the 800 level the massive sulphide in the Copper Rock claim shows a greater percentage of bornite and chalcopryrite. The developments around raises 188 and 195 indicate a flat lense of sulphide ore assaying 5½% copper for 80 ft. with the face going south in the same ore.

Prescott.

For some time past the Oro Belle Development Co., a corporation dominated by E. J. Riggs, M. G. Bradshaw, C. C. Cowan and Eli Perkins, has been operating profitably the holdings of the Tiger Gold Mining Co. in the Crown King country. Recently, however, the property was sold to H. O. Howard, a Nevada mining man. Howard in turn has interested New York capital in the venture and is now in New York arranging for mining operations on a more extended scale than formerly. The plans include the erection of a mill, the opening of the mine at greater depth and extensive exploration in the ore bodies already exposed. The old Tiger Gold is one of the bonanzas of former years and has to its credit an ore production of nearly \$2,000,000. At depth, however, the ores became base and failed to respond satisfactorily to the treatment processes of the past and the

mine was closed down. The success which attends reduction by the oil-flotation process has again given the Tiger Gold ores a commercial value. Bradshaw, Riggs and associates have been handling these ores at a profit for a number of months in the small mill at the property and will continue to do so until such time as Howard inaugurates his more comprehensive mining and milling plans.

Connection of the two main levels in the Nelson mine affords 500 ft. of backs, or stoping ground, and puts the property in line for immediate production. The ore now being mined carries a gold content in excess of \$25 per ton and is being saved for shipment. The property has been undergoing development for nearly 3 years and is considered one of the most promising in the Crown King section. In the near-surface levels very high-grade gold ore was from time to time discovered. Now that the continuation of these ore bodies at depth has been demonstrated it would appear as though the Nelson was in line for a large and regular production.

Reorganization of the Cash Mines Co. has been perfected through N. H. Getchell and a development fund of \$200,000 subscribed. New York and other eastern capitalists are back of the reorganization plans and will visit the property immediately after the election. The Cash mine is located beyond Senator in the Groom Creek country, and is one of the country's best known gold propositions. Getchell has opened it at depth and has exposed a large tonnage of pay ore. During the past 6 months five mining engineers have examined the property and made favorable reports thereon. In each report the recommendation was made that electrical appliances and an oil-flotation unit be established at the Cash mill. These recommendations are to be acted upon at once and will be followed by the reduction of 100 tons of ore per day. The plans of the company likewise include the sinking of the main shaft to greater depth.

The 50-ton mill recently installed at the Arizona property near Humboldt by the Arizona Mines Supply Co. of this city has been in operation for the past 2 weeks, and is successfully treating the mine product. High-grade concentrates are being recovered and shipped to El Paso. The Arizona is owned by F. M. Anderson and Sidney Birch of Prescott, and has for many months been in the productive class while undergoing development. During that period 21 carloads of silver-gold ore were shipped to El Paso. Hereafter, however, only the concentrates will be shipped. The mill will reduce all ores mined and has been tested sufficiently to insure a high saving of values. A large tonnage is on dump and blocked out in the mine workings, and is said to be a better grade in the lower levels than in the near-surface levels. Until Anderson & Birch took it over the mine had been idle for about 25 years.

A large and modern plant of machinery, including a Diesel engine and 5-drill air compressor, is being set up at the old Octave mine in the Congress country. Additional machinery is en route. It includes an oil-flotation unit and the other equipment requisite for reducing the large tonnage of ore that has been opened up during the past 3 years. About 4 years ago a group of Boston mining men acquired title to this old-time producer under bankruptcy proceedings. Since then the main-working shaft has been deepened and levels established to a depth of 1200 ft. Drifts and crosscuts have been run on each level and gold ore has been blocked out. The development work of the past 15 months has been especially prolific in the opening of commercial ore.

Within 30 days a new plant of machinery will be in commission at the Last Chance property in the Walker district and development work again in force. The plan includes a hoist, air compressor, jackhammers, ore cars, track, etc. C. B. Hayes is backing the venture personally. Crosscutting from the main shaft has exposed a large deposit of pay gold ore through which pass bands, or lenses of exceptional value. Hayes had expended a large sum in carrying out his development plans.

John Harlan, superintendent of the Crook mine, reports steady mining and milling operations and the shipment of concentrates to El Paso at frequent intervals. The Crook tunnel has a length of 1800 ft. at this time and is being driven with three shifts. The face of the tunnel is carrying an

excellent grade of gold ore and values are holding strong as it is advanced. A large tonnage of pay ore is in sight and the general situation at the property very encouraging.

New machinery has been installed at the Beehive property and development at depth is well under way. The property adjoins the Octave mine on the east and is located on the rich Octave fissure. The mineral content is gold and is increasing in value as development progresses.

The usual daily production of 80 tons of copper ore is being maintained at the Commercial mine in Copper Basin and is being regularly forwarded to the Humboldt and Clarkdale smelters. S. L. Landon recently assumed charge of the mine as assistant to Major A. J. Pickrell.

D. A. Burns of Oatman has assumed charge of the Mint group in Copper Basin and is shaping the property for extensive mining operations. The workings are being unwatered and as soon as this work is finished the drift on the 200 level will be extended to pick up an ore shoot that gave high gold returns at surface and nominal depth. Burns recently acquired ownership to the Mint group and has the financial resources necessary to thoroughly develop it.

Chloride.

The power line being constructed by the Desert Power & Water Co. is now within 5 miles of Chloride. The line is being built at a rate of half a mile a day, so that in 10 days it ought to be very close to town.

E. M. Binds, a mining engineer of Los Angeles, is here to direct the commencement of operations on the Emerson, adding still another property to the long list in active operation here.

A road is being constructed from the mouth of Alum Wash to the Black Jack mine and an extension of this road is being surveyed to run from the Black Jack to the Gladstone. The entire road will be about 2½ miles in length, and will serve several other good prospects in the east section of the camp.

The Black Jack ore has commenced to go through town on its way to the smelter. The ore is being packed by burros from the mine to Tramway landing, thence by wagon to the railroad.

The water company plans extensive improvements and extensions to accommodate the fast growing town. A new reservoir is to be built at the head of Tennessee avenue to give the camp better pressure for fire-fighting. More cross-mains are to be laid in the north and south sections. The camp is spreading mostly in a southern direction, along the new boulevard now being built by the county, and this section is compelled to rely upon the water wagon for its water supply.

CALIFORNIA.

Jackson.

Deputy U. S. Marshal Otis Bohn and attorneys representing the mine operators have served injunctions on 100 striking miners, restraining them from interfering with working of the mines. This follows a recent order of the U. S. District Court at San Francisco. An injunction has also been issued against Assistant State Labor Commissioner J. J. Kelley. Attorneys in the employ of the Western Federation of Miners will represent the strikers when the temporary injunction comes up for argument.

Large numbers of strikebreakers are coming into the district, and it is evident the operators will make a determined endeavor to resume operations. All the mines remain idle, with the exception of the Plymouth Con., at Plymouth, and the old Eureka, near Sutter Creek. Several clashes have recently developed, but the strikers have been generally peaceable. Pumps are still idle at the South Eureka, but the miners have agreed the company may keep the mine unwatered.

Grass Valley.

A meeting of stockholders of the Union Hill Mines has been called for the purpose of dissolving the corporation and distributing treasury funds; \$85,000 remains in the treasury,

after meeting all expenses. New interests recently took over the property and are operating it at a profit. Rich tungsten ore continues to be mined, and driving is proceeding with a view to intersecting the Georgia and Union Hill veins. Additional territory has also been acquired.

General Manager C. K. Brockington of the Golden Center and Grass Valley Mines companies has placed orders with local foundries for a 10-stamp addition to the Golden Center 10-stamp mill, and a complete 20-stamp plant for the Allison Ranch mine. The shaft of the Golden Center has been completed to a depth of 1000 ft. and drifts are advancing along shoots of rich ore. Unwatering of the Allison Ranch is proceeding slowly, and the new pumping system is to be in service about Nov. 10. Construction of the mill and mine buildings is making good headway.

Bishop.

Heavy shipments of tungsten concentrates are being made regularly by the Tungsten Mines Co., a shipment last week being valued at \$20,000. Eleven concentrators are running with three shifts employed. At the Little Sister mine surface ore is being quarried, and good ore opened in the tunnel workings. Howard Moore has been appointed superintendent.

Considerable work is going on in the Standard group, where some excellent tungsten ore has been blocked out. The company is erecting new buildings and bringing in winter supplies. It is planned to continue work throughout the winter months.

Sonora.

Rich quartz has been intersected in the drift from No. 1 winze in the Omega. The discovery was made about 25 ft. below No. 1 level and shows a 9-ft. vein containing broad shoots of ore averaging better than \$200 per ton in free gold, with considerable sulphurets also present. The ledge is broadening as drifting advances, and the discovery is considered a most important one. The mine formerly yielded much bonanza and at this time is operated under bond and option by Lange & Hussey, understood to represent New York people. C. W. Ayers is manager.

Additional concrete bases and foundations are being installed at the Dutch mine and mill for support of new equipment. The milling plant is being improved and enlarged. The Dutch, App and Sweeney properties are worked through the Dutch shaft and late important developments have warranted the installation of much new machinery.

The Black Oak Co. has installed a diamond drill on the 900 level and has arranged for extensive explorations below this point. Rich ore is coming from the main levels. The Confidence Gold Mining Co. has been formed to take over and operate the Confidence mine. Satisfactory developments will be followed by installation of new equipment.

The McAlpin Mines Co. is opening excellent ore in its property at McAlpin in the southern end of Tuolumne county. The vein is 4 ft. wide and assays \$90 in gold. The strike was made near the 500-ft. point and about 700 ft. of backs are available along the strike of the new ledge. Frank P. Whitcomb is president.

Heroult.

Three furnaces are running steadily at the Heroult electric smelter, producing ferromanganese, ferrochrome and ferrosilica. The company is devoting particular attention to development of manganese deposits, finding it difficult to supply the demand for ferromanganese. Another furnace will be operated on this product as soon as sufficient crude ore is assured. Most of the manganese is coming from points tributary to Hollister, Ukiah, Castella and Livermore. Ore from the Castella district is especially favored, as it is near the plant and means an important saving in freight costs. Deposits near Callahan are considered promising. No attempt will be made at production of pig-iron while the demand for other products remain satisfactory.

Mokelumne Hill.

A bond has been taken on the Sullivan quartz mine in Chili gulch by H. J. Windler, general manager of the Mokelumne group. The property has been opened by a 450-ft. tunnel, which shows a strong ore body 14 ft. wide. The tunnel is being extended and drifts started. The adjoining

Lancell gravel property has also been reopened under bond. The tunnel strikes the noted Stockton Ridge channel.

Angels.

The Angels Camp Deep Mining Co. has installed a compressor and is sinking the shaft with air drills. At a depth of 140 ft. excellent ore is showing, with the vein improving as depth is attained. It is planned to erect a small mill to take care of ore broken in routine work, and to provide a large plant as soon as ore conditions warrant.

Sutter Creek.

A 9000-gal. tank has been installed on the 500 level of the Old Eureka, to take care of water raised to this point from the deeper workings. A centrifugal pump elevates from tank to surface. Unwatering of the 800 level is making good progress and the workings have been found in better condition than anticipated. The management is confident of starting mining early in 1917.

Dutch Flat.

The Rawhide mine has been reopened by the Canon Mines Co., after lying idle 5 years.

COLORADO.

Cripple Creek.

Thirty tons of ore from the Isabella Mines Co. carried a value of \$197.47 per ton, a gross bullion value of \$5,923.50. The ore was mined on company account from the ore shoot under development at the 15th level of the Lee shaft.

A winze sunk 125 ft. below the bottom level of the Cresson Con.'s main shaft has proven ore values continuous to that depth. Work will shortly commence on a lateral to be extended from Roosevelt tunnel directly under the Cresson shaft. A raise will then be carried to connect. The bottom of the winze is 160 to 175 ft. above the tunnel level. This lateral extending in a general northwesterly direction from the line of the drainage tunnel through Raven hill will be important exploitation work.

The shaft on the Little May claim has been timbered by the Cripple Creek General Mining & Exploration Co., and sinking has been resumed. It is expected that the Josephine vein will be cut on its dip in the next 15 or 20 ft., as values are already carried in feeders cut in the shaft. The Little May shaft is equipped with a windlass only. With a depth of 50 ft. an electric hoist will be substituted and a shaft house constructed.

Rico.

Rico shipped 11 cars of ore during September. The falling off in tonnage is due chiefly to the fact that the Rico-Wellington has nearly discontinued its heavy shipment of low-grade and is directing efforts toward the production of higher grades. A new series of ore beds may be encountered at any time as the extensive development operations there proceed. Lead-silver ores now predominate in the output, as was the case in the best days of the camp. September shipments were: Rico-Wellington, 5 cars lead-silver to Leadville; 2 cars copper-sulphide to Leadville; 2 cars lead-carbonate to Durango. Rico-Con., 1 car copper-sulphide to Leadville. W. P. Muncaster & Co., 1 car lead-copper to Durango.

A night shift has been put on at the Rico-Argentine, and a force of 20 men is now employed. Since the installation of the new power drill equipment good headway is being made.

The Rico-Wellington has a record of 684 ft. of work for the month of September. This is a remarkable showing. The mine is reported as being in splendid shape, with ore prospects excellent.

Leadville.

The water level in the Mikado is now down to the 900 level and the shaft has been retimbered to that point. A new and larger station is being cut in the shaft which when finished will be 15 ft. wide, 18 ft. high and 60 ft. long. It will accommodate the main pumping equipment to be installed on surface. The blacksmith and machine shops have been completed. Foundations are being put in for the new hoist

and compressor, which are expected to arrive within the coming week or ten days. The hoist will be of exceptional size.

The Wolfstone shaft has been drained to the 1000 level, being aided by the pumps in the Greenback, which is 230 ft. deeper than the Wolfstone. The Greenback is now pumping the remaining 230 ft. of its shaft. The draining of the Greenback will unwater the greater part of the Pyrenease basin to a depth of 1350 ft. It will allow extensive development to be carried on through the Emmet, Wolfstone, McCormick and Greenback, which are located in this section. The developments planned for these properties are the first steps to be taken toward deep mining on a large scale in the district.

The Wyoming Valley Tunnel is being driven under contract to Chapman & Smith to reach some of the well-known producing mines that lay ahead. The next vein to be encountered will be the Niagara, which will be reached in 200 ft., then the Artilleryman, Golden Era, French Flag and Silver Age Extension. When this group is reached, large bodies are expected.

Boulder.

The Cash mine is to again be operated. Compressor, air drills and other machinery have been installed. The policy will be to operate the ground under the leasing system. Several lessees have already taken ground and are now ready to operate.

Telluride.

The Carruthers mill will be ready for operation about Nov. 1 and the tramway between Sheridan tunnel and the mill will be in readiness to bring the ore from the Carruthers vein. The mill will have a capacity of 60 tons. The ore is treated with a ball mill of this capacity, and it is free milling ore of a good grade. In order to conserve the water for milling purpose the management has made three small storage tanks; one is 6 by 8 ft., one 8 by 12 ft., one 12 by 12 ft. Added to this supply is that from Royer creek taken from the hillside above the mill and pumped up from the gulch below the mill with an electric pump. The mill will be driven by electricity.

IDAHO.

Wallace.

The Columbus Mining Co., recently organized, has purchased from Edward P. Gallagher of Philadelphia, Pa., the Columbus group of claims, in the Eagle mining district of Shoshone county. The holdings comprise the Columbus, Mary, Good Hope, Murray, Wampum, Dinero, Plumbum, Argentum, Good Luck, Gallagher, Colonel Bradford, Golden Eagle No. 1 and Golden Eagle No. 2 claims, adjoining the Jack Waite and Samson groups.

Announcement has been made of the sale of 200,000 shares of treasury stock of the Rob Roy Mining Co., which owns and is developing the Rob Roy group. The proceeds of the sale will be devoted to further development of the property, according to O. W. Lewis, secretary of the Rob Roy Co. "For the first 50,000 shares we received 15 cts., for the second 50,000 we got 25 cts., and the remaining 100,000 will bring us 40 cts.," said Mr. Lewis. "The purchasers are eastern men, who already have made the first payment, and the remainder will be paid next week. The money will be used to install a compressor and to carry out a comprehensive plan of development. The tunnel is at the 800-ft. point, and followed the vein part of this distance, exposing mineral. It will be continued 1300 to 1500 ft. The property comprises seven claims and adjoins the mine of W. A. Clark, but is on a different vein."

Shipments will begin from the Rex mine, in the Nine-Mile district, not later than Nov. 10, unless there is further delay in the delivery of equipment that has been ordered for the mill, according to Raymond Guyer, who recently succeeded President M. J. Sweeney as general manager of the Rex Con. Co. It was announced several weeks ago that production would begin Oct. 15, but the Riblett Tramway Co. of Spokane, which has the contract for installing the new aerial tram, connecting the mine workings with the mill and the

shipping bins, has been unable to secure buckets for the carrier. "We also are installing two new crushers and a new sorting belt, and part of this equipment has not arrived," said Manager Guyer. "We anticipate having the delayed machinery on the ground not later than Nov. 1, however, and it will require but a few days to place it and get it ready for service. We first contemplated utilizing the old tramway, which had been removed to the Tamarack & Custer mine, when that property was served by the Rex mill, but later we decided to put in an entirely new carrier, and this necessitated postponing the date of beginning shipments. We have had to erect 19 new towers, but these have been completed and the cable strung, so that it will require but a few days to attach the buckets when they arrive. Needed improvements in the mill have been made while we were waiting for the additional machinery, and the plant now is in splendid shape for continued operations." It is stated officially that there is a considerable tonnage of ore broken down in the stopes, ready for immediate extraction when the mill is in commission, and it is estimated that there is not less than 12 to 18 months' supply for the plant operating at the rate of 200 tons daily. All of the undergrounds that had been flooded during the 5 years that the property was idle have been unwatered and repaired, and there has been a great deal of new development on both the Rex and Okanogan veins. The power house, burned more than a year ago, has been rebuilt and new and larger electric motors installed. Other camp buildings have been repaired and material and supplies for the winter's campaign have been assembled. Manager Guyer states that the physical condition of the property is better than ever before, and he anticipates no delays after production is inaugurated.

Mullan.

Development of the American Commander Co.'s claims is revealing promising conditions in the tunnel now being driven, and the formation indicates the proximity of an ore shoot, according to E. J. Clarke, president. "Several stringers carrying lead have been encountered in the tunnel, and these, we believe, indicate that the bore is nearing the vein," said Mr. Clarke. "The face now is but 300 ft. from a point below the 75-ft. surface shaft that was sunk on the ore several years ago, but, as the vein rakes toward the crosscut, it is probable that it will be encountered sooner than we first estimated. The ore body traverses our ground its entire length, and we will have attained not less than 600 ft. vertical depth when the ledge is reached."

Kellogg.

The directors of the Caledonia Mining Co. on Oct. 24 declared the regular monthly dividend of 3 cts. a share, or \$78,150, payable Nov. 5 to stockholders of record Oct. 25. This will make the disbursements for the current year \$833,600 and will increase the grand total to \$1,716,331. The company is capitalized for 2,605,000 shares at \$1 each, and control of the corporation is vested in the Bunker Hill & Sullivan Mining Co. The company's net earnings in September were approximately \$100,000, according to President Stanly A. Easton, as compared with about \$90,000 in August. There have been no new developments in the Keating tunnel, where search is being made for the faulted ore body, but the work is being continued.

Hailey.

The Wilbert Gold Mining Co., which owns and operates a property in the Wood river district, has declared a dividend of \$10,000, payable Nov. 15. This will make the total payments \$50,000 since disbursements were inaugurated a little over a year ago. In a report accompanying the dividend announcement Manager H. S. Knight states that there are \$13,000 in the surplus fund, and that this is being increased from month to month. There are about 30 men employed in the mine and mill, and in addition to active mining operations the company has inaugurated extensive development.

Burke.

Development of the east vein in the Hecla mine has resulted in opening one of the greatest ore bodies ever encountered in the property, according to reports, and, while official confirmation of the discovery can not be secured, there is little doubt but that the reports are correct. The new ore body is said to practically double the resources of the

mine and to be equally extensive and as rich as the original Hecla vein, from which the company to date has paid more than \$5,000,000 in dividends, besides building up a surplus fund of approximately \$600,000. It has been proven for a distance of 850 ft. on the No. 3 level, from which an upraise has been run 600 ft. on the ore, the most of which is said to be lead-silver, much of it steel galena, with only occasional traces of zinc. The recent exposure was made in the 900 level, which is 900 ft. lower than the No. 3, where a crosscut opened 4 ft. of high-grade ore, and the opposite wall has not been reached.

Osborn.

The new mill of the Silverado Mining Co. will begin operations in a few days, according to C. D. Muxen, secretary-treasurer of the corporation. The plant was designed and construction supervised by W. L. Ziegler, superintendent of the Success Mining Co.'s concentrator, who will be in charge until the equipment is adjusted and operating satisfactorily. The mine and mill are under the management of Dr. W. H. Farrar, who 50 years ago erected the first stamp mill at Warrens, packing the entire equipment on muleback a distance of 120 miles. The Silverado holdings have been developed intermittently for many years, but in recent months the work has been of more permanent and systematic character. The mill and the 2-phase 5-drill Ingersoll-Rand air compressor will be driven by a 75-hp. motor, actuated by current from the Washington Water Power Co.'s nearby transmission line.

LAKE SUPERIOR.

COPPER.

Houghton.

Cherokee is in good copper, better than has yet been found at the depth of 118 ft. A crosscut is being driven to ascertain the width of the lode, and its mineral contents, after about 4 ft. had been blasted off at the top of the ledge, the width was 47 ft., and the metal of heavy grades, quite uniformly distributed. It may be possible that one drill would be set to drifting, but this is not considered likely at the present, it now being the intention of the management, when the crosscut and sump are completed, to continue sinking.

Flint Steel has received a boiler and will get its pump this week and soon begin to unwater its old workings on the Butler lode. A small building is being erected for the men. At No. 6 shaft the water is below the surface about 60 ft. and the workings there give signs of considerable copper.

Michigan, at the distance of 404 ft. from the Butler lode, is in a lode which, from its location and character, seems to be the Evergreen, but the disclosures are rather light and infrequent. The fissure vein that parallels the Ogimah a few feet from it on the hanging-wall side has been entered with good disclosures. As soon as it has been crossed the good streak on the hanging wall of the amygdaloid will be returned to, where the ground was of excellent values when the crosscut was begun.

New Arcadian has arrived at the 1500 level and will begin its two crosscuts about the 27th, one going east 150 ft. to the New Arcadian lode and the other west a few feet to the lode met with behind the shaft about 16 ft. on about all of the levels. The drifts at the 150 level, or bottom, at No. 2 shaft, are displaying a very good quality of metal. The work on the new rockhouse will not be ready for about 4 weeks.

New Baltic is down about 35 ft. with its shaft pit and has yet no sign of the ledge. It is thought that the ledge will be struck within 15 ft.

Mayflower and Old Colony have ended their diamond drilling, as about all the needed data have been obtained. No conclusion has yet been arrived at by the management of the two companies as to the consolidation, which is considered by the friends of each as a necessary preliminary step to a proper development.

Mass is getting quite a large number of men now, and with the completion of the repairs on the crusher at "C" the

output that had fallen off to below 1000 tons daily will be gradually brought back to over 1200.

South Lake has been obliged to proceed slowly with its increase of tonnage, owing to the necessity of installing an aerial tramway to carry the waste rock over the railway track; this will be completed within a few days.

North Lake is driving the crosscuts both ways and has covered a distance of over 500 ft. on each side, finding nothing of promise. This work will be continued, as there are the North lodes of the South Lake to be reached on the north-west side and several lodes found by diamond drilling on the southeast.

Indiana has on the lode supposed to be the Butler reached a depth of 50 ft. and is finding some copper with an occasional piece of commercial grade.

Franklin is gaining slowly in tonnage and is keeping up near the 1100 limit, as there are some more men to be had. The property is earning about \$30,000 monthly and will soon have enough money ahead for improvements at the mill.

White Pine Extension has at the 200 level been drifting for some time, and is ascertaining that the values in the beds at this point are continuing. Only enough work is being done now to prepare for a flotation mill that will be begun early in the spring, the necessary outfit being manufactured during the coming winter. From the experimental work so far done there is no doubt of the success of this system.

La Salle is sending to the Franklin and Ahmeek mills very nearly 500 tons of rock daily, only about 20 cars a week going to the latter. It is sinking below the 19th level at No. 2 shaft and is drifting on each level from the 12th, where profitable values were first encountered, to the 19th, inclusive, no stopping being done at this shaft.

Ahmeek has so far on the 10th level on the Kearsarge conglomerate 110 ft. of drifts that average very good, and the indications of the faces of both drifts are very favorable. After a while another crosscut will be driven to determine the width of the mineralization. The work on the new steel No. 2 shaft rockhouse has been so delayed that it will not be finished for some time on account of the great lack of good surface men. The new fissure at North Ahmeek, shafts Nos. 3 and 4, though it has not been opened enough to make certain of its persistence for any length, is equal in richness to the fissure at No. 2 which, for about 4 years, has been of such great value in increasing the yield of the mine.

Allouez is back again after a small decrease in its tonnage, due to the scarcity of trammers for a short period, and is hoisting daily its normal for the present, about 2000 tons.

Calumet & Hecla is doing much better in the way of daily tonnage than for some time, and is milling 10,600 tons daily. It is thought probable that this rate can be maintained for some time, as undoubtedly more men are coming into the district. This month, owing to increases at the Mohawk and the Calumet & Hecla and some of the smaller properties, the tonnage will be slightly greater per daily average than in September.

Osceola will have about the same tonnage for this month as for September, about 109,000 tons. The last few days the daily tonnage has had a slight increase, but more men could be easily employed at all three of the mines branches.

Mohawk has been doing much better in getting men and swelling its tonnage, and in fact it is now running to its capacity, and was obliged to operate the mill Sunday, the 22nd. It is averaging very close to its normal, which is the highest possible capacity. There has not so far been any increase at the Wolverine, but this mine will probably join the procession in a short time.

Adventure has its bailers running and has drained out the 3rd level, where the old workings have been thoroughly examined and a very fair showing of metal found. It is most likely that other levels will be unwatered before any mining is begun.

Lake has its hoist and shaft now in good condition and the old workings on the Knowlton lode are being gone over and some drilling will soon be started. The copper contents as indicated by the walls of drifts are quite promising.

IRON.**Hayward.**

Proving an iron formation of commercial value in Sawyer has been taken up by the Edson interests of Duluth and drilling has been started east of this city. The work of proving a formation in northern Wisconsin has been started several times, but never completed. Another drill has been started by a syndicate just north of Weyerhaeuser. This same syndicate sank 5 holes east of Murray some time ago, but results were never made public.

Tramp ore steamers in Lake Superior are being gotten together to transport the product late into the season. It is said they are contracted for at twice the usual price of 50 cts. per ton, or \$1. Much iron ore has been contracted for into the spring of 1917. The Atlantic coast furnaces, which heretofore have obtained all of their supply from Cuba and eastern states, are purchasing some ore in the Lake Superior district at present. Estimates for the 1916 season are placed at between 60,000,000 and 65,000,000 tons shipped.

MISSOURI-KANSAS.**Joplin, Mo.**

There was a renewal of the optimism that has been a part of the zinc mining industry for the past year, when this week's ore prices again advanced sharply, registering \$75 base for both first and second-grade ores. All along the line there was a strong demand, and calamine as well as blende profited by the strength of the market. Lead ore prices were equally strong with zinc, and 80% lead brought as high as \$87. At these prices naturally there were heavy sales of ore, and the week saw many bins sold and moved out as rapidly as the smelting agents could move them. In the Miami camp, where so much of the surplus stock has been held, there were especially heavy sales, and as much as 3000 tons of the surplus stock in that camp are reported sold, with rumors of still other heavy sales as yet unverified. If this proves true there will be great rejoicing in the district, for the removal of these stocks at \$75 prices means profitable operation, and greatly improves the local situation from a market standpoint. It is these stocks that have held down the market so strongly, locally, for some time past.

But with these good prices prevailing it would appear that every effort would be made to increase production, and this is true, except that there are many interfering conditions at this time, and conditions that are likely to grow worse instead of better with the coming on of the winter season. The lack of power by the electrical power company is a serious handicap for many of the mines, and there seems very little possibility of this being improved for some time to come. The inability of the company to get deliveries upon new electrical units under a year's time, coupled with already crippled plants, would seem difficult enough, but on top of this is the serious state of the district's streams, which, owing to the lack of rains, are so low as to cut off a good portion of the company's power from its water power plants. It would seem that the elements are conspiring to thwart a larger ore production from the field, for in addition to the lack of electrical power, is the acknowledged shortage of gas for even domestic use, much less for power engines and under boilers, and this means a total readjustment of power in many of the district mills and mines. The falling back upon coal, while the only alternative, is not altogether satisfactory, for of that fuel there is not a satisfactory delivery nor a surety of supply during the winter months. Every operator is trying to stock up on coal, and has orders in for many carloads, but is finding that his having it ordered is about his only satisfaction, for he is not receiving deliveries in anything like proportion to his orders.

Webb City, Mo.

Hornbrook & Federman of Kansas City have brought the production of the Old Yale mine up to 2 cars of concentrates per week, while in their new mine at Duenweg, which is called the Mahatma, the production has now been brought to 1 car per week. The first property is a sheet-ground mine, well opened up with a mill of very large capacity upon

it, while the second is a soft-ground property, with a smaller milling plant, and it is only in the earlier stages of development.

At this week's regular meeting of the mine operators at Webb City the following delegates to the American Mining Congress were named, and it is believed that there will be others before the meeting is held: W. B. Shackelford, Geo. J. Kusterer and Otto Ruhl were named as the ore producers' delegates.

The Near By Mining Co., holding a lease on a portion of the Center Creek ground at Webb City, has started the construction of a mill, having purchased the L. J. Steverson plant at Porto Rico, and is moving it to the new location. The plant, when remodeled and built, will treat 450 tons of ore per day. Those interested in the new company are W. E. Patton of Webb City, E. S. Williams, L. S. Durham, John O'Keefe and B. L. Van Hoose of Carthage.

The new Yellow Jacket mine at Duenweg has started operations after a shutdown of several months for a prospecting campaign, which has netted them a very promising ore body. The prospecting was conducted by drilling, and five good holes were put down. The drifting has been started to open up the new discovery. N. S. Snow is superintendent of the property.

The Hartford Mining Co. has just started the erection of new concentrating plant on a well-developed 35-acre lease in the Porto Rico camp. The new plant will be a modern 500-ton capacity, and while in part constructed of old machinery, will have new jigs, new tables and very much new material in it. While the mill is being erected the underground development work is being hurried forward. Two shafts are being recribbed and concrete lining is being used. H. H. White of Joplin is the general manager of the property.

MONTANA.**Butte.**

The Ophir mill of the Butte-Detroit Co. will be reconstructed to operate on zinc-silver ores from the Davis-Daly, using the flotation process. Bins have been built at the Davis-Daly, together with a number of chutes, and everything is in readiness for the mining of zinc ore. Above the 1700 level a half dozen faces of zinc ore, each of a width from 6 to 10 ft., have been opened, and assaying from 19.50 to 39% zinc, with from 9 to 15 ozs. of silver and carrying an iron content ranging from 1.5 to 5%. The Ophir plant will start with a capacity of from 100 to 150 tons daily. Test milling runs on the Davis-Daly zinc ores show a recovery at the Callow flotation plant in Salt Lake of 95%, with concentrates carrying 52.75% zinc, about 2 lbs. of oil to the ton being used. Tests made at local flotation plants show a recovery as high as 97%, the concentrates carrying 55% zinc.

Two veins have been crosscut within the past few days on the 1000-ft. level of the Butte & Zenith City, according to Supt. William Gibson. One fissure opened in the south crosscut 91 ft. from the shaft shows a width of 10 ft. of well mineralized ledge material without any sign yet of the other a half of 1% copper, which, while not in itself commercial, is regarded as indicating that the company is in the copper ore zone. The other fissure has been cut in the north crosscut, 135 ft. from the shaft, the breast being in 10 ft. of mineralized ledge material without any sign yet of the other wall. This ledge was cut Saturday and assay returns have not yet been received. The sulphide vein is about 200 ft. south of the shaft and it is expected to reach this fissure about Nov. 1. It will be necessary to go about 400 ft. north before the vein is cut.

Along with the dividend checks of the North Butte Mining Co. there was received here this week the quarterly report of the company for the term ending Sept. 30. The report shows that during the past 3 months there has been 5562 linear feet of development done. The features of the quarter's work have been the proving of the eastward extension of the ore body on the 2200 level of the North Berlin vein. The finding of ore on the 1800 in the same vein and the cut-

ting of ore on the 2000 level of the Adirondack vein. On the North Berlin vein on the 1800 level a crosscut has encountered the vein and drifting has been done for a distance of 47 ft. in ore of an average width of 3½ ft., assaying 3% copper and 8 ozs. silver. On the 2200 level of the same vein development work has been extended to the east, the drift advancing 184 ft. in ore of an average width of 4 ft., assaying 7.5% copper and 16 ozs. silver. The significant feature of this vein is the high silver and copper values of the ore. Crosscuts are approaching the vein on both the 2000 and 2400 levels. It is announced that during the present quarter development work will be pushed on three new levels below the 3000 level from the Granite Mountain shaft and on the North Berlin and Adirondack veins, as well as other veins now being mined. During the quarter there were mined and shipped 128,040 wet tons of ore and 46 wet tons of precipitates and there were treated 124,454 dry tons of ore and 34 dry tons of precipitates, of which ore 17,108 dry tons, or 13.7%, were first-class and 107,346 dry tons, or 86.3%, were second-class. This produced 5,953,685 lbs. of copper, 247,833.14 ozs. of silver and 402.53 ozs. gold. The financial statement shows copper and silver on hand to the value of \$2,298,014.17, while the surplus and reserve amount to \$4,789,369.27.

Troy.

The extensive construction work and development that is being done by the Snowstorm Mines Con. Co. is inducing activity among other companies operating in the region surrounding Troy, and the district is now the center of greater operation than at any time in its history. The Togo Co., Ralph Smith and Robert Larter owners, has started a tunnel that now is in 200 ft., and will be continued 600 ft. to reach a body that is 2 ft. wide at the surface, and contains silver-lead ore of high grade, and no zinc. Some of the ore runs 400 ozs. of silver. The construction of a flume to carry water to drive a compressor is nearly completed. Cabins and a road are being built by the L. & V. Mining Co., a Spokane corporation, in preparation for development throughout the winter. The property is a northerly extension of the vein system of the Big Eight, owned by Harry L. Day of Wallace and the Snowstorm Con. The Silver Tip Co., owned by Robbins & Wright of Spokane, has let a \$9000 contract for 900 ft. of crosscutting that is expected to reach the vein at a depth of 600 ft. The shoot contains silver, lead and zinc. J. H. Ehlers, identified with the Sylvanite, a gold property, 20 miles north of Troy, reports that operations to be started this fall will proceed through the winter. The company has ordered a carload of horses to haul lumber for the establishment of a large camp. Winter quarters have been completed by the Montana Morning, and drifting is in progress. The property is comprised of 12 claims, traversed by three parallel leads opened by several hundred feet of tunnel and two shafts. All of the veins show good values in silver, lead and zinc. Development is being directed by William Hogan of Spokane, who, with Bud Woods of Troy, is the chief owner. The Snowstorm railroad crosses the north end of the group.

NEVADA.

Goodsprings.

The management of the Boss Mining Co. is perfecting details for the new mill. Experiments with the testing plant indicates a high extraction of gold and platinum can be made at a comparatively low cost. The projected plant is designed to treat 10 tons daily; 800 sacks of high-grade platinum ore are ready for treatment. Ore running 25% has been intersected in No. 6 winze and work has begun in No. 4 tunnel to open the vein to advantage.

A 9-ft. vein of rich ore has been encountered in the Oro Amigo, assaying approximately 40% copper, \$25 gold and \$45 platinum. The discovery has stirred considerable interest and is believed to demonstrate the presence of important platinum deposits outside the Boss acreage. Sinking and raising along the vein are proceeding.

A 2-ft. ledge of ore assaying 60% lead and carrying considerable silver has been intersected in the Sweepstakes claim,

owned by J. Madison and Arthur Kunze. Sinking is advancing with the ore body showing strength. Important zinc discoveries are reported from the Anchor, Root and Potosi mines. The latter is owned by the Empire Zinc Co. and was examined last week by Capt. C. J. Brown, western manager for the company.

The Dawn Mining Co. has resumed operations. Some rich zinc ore was lately intersected and work is proceeding to determine extent of the deposit. The property lies on the eastern slope of Potosi mountain, in a promising ore belt. Albert Munzberock is superintendent.

Bert Whitney of St. Thomas has secured a lease on the New Year claim and is arranging for installation of a hoist and building of ore bins. Some excellent ore is exposed. Dan A. Potter and Frank Tursick report a promising copper-silver discovery in the Copper Metal property. Samples assayed in Goodsprings returned 34% copper and 38 ozs. silver.

Searchlight.

This district is showing considerable activity after several years of indifferent development. G. F. Colton has arranged for resumption of work at the Duplex, formerly a good producer. The shaft of the Big Casino is being deepened 10' ft. on a strong ledge of concentrating ore. Considerable new work is going on in the Quartette, and it is understood 100 men will be employed in the near future. The mine recently passed into the hands of a strong New York syndicate. The Searchlight Mining & Milling Co. is preparing for developments along broad lines. Several companies are preparing for work on holdings north and east of the camp.

The El Dorado canyon section of the district is exceedingly lively. A new camp known as Nelson has been established at a point about a mile east of the Wall Street mine, and is growing rapidly. It contains about 50 structures of all sizes and descriptions, including general store, postoffice and lodging houses.

At a depth of 20 ft. in the Carnation property a 40-in. shoot of gold-silver ore has been encountered, assays averaging around \$76 in gold and 28 ozs. silver. Sinking is proceeding with the vein slowly widening. On adjacent ground the same vein has been intersected by the lease operated by Matt Fisher of Las Vegas. The Carnation is operated by a leasing company composed of V. H. Welk, C. O. Spencer and W. A. Kirchner of Goodsprings.

Sinking in the Eldorado Empire is proceeding to tap two cross veins, one being the noted east-west ledge of the Wall Street. C. E. L. Gresh is manager. Other active properties are the Eldorado Nevada, Enterprise-Rand and Cluff-Era. E. P. Jeanes is manager of the Enterprise-Rand Co.

Winnemucca.

A new camp, known as Wallace, has been established about 10 miles southeast of Winnemucca, and approximately 5 miles from the Southern Pacific station of Rose Creek. Two gold-silver veins have been uncovered, and at a depth of 20 ft. a 6-in. shoot of \$200 ore is exposed. Shipments are to be made in a few days. The property is owned by Robert Wallace and Henry Kantewein. Leases have been taken by E. D. Rogers, Hartman & Truitt and Abel & Loinaz.

Goldfield.

The Silver Pick Co. is crosscutting at an approximate depth of 1000 ft. to intersect rich shoots exposed in the two contacts by core drilling. High assays are reported at several points, and within 500 ft. the management anticipates developments of importance.

NEW MEXICO.

Mogollon.

The Oaks Co. milled another lot of ore during the week, taken from development work on Clifton mine.

Socorro Mining & Milling Co. shipped 1800 lbs. gold and silver bullion from operations covering first half of October.

Timbering of new shaft below 500 level has been started at two separate points by Mogollon Mines Co. During the

week 980 tons of ore were treated and 1500 lbs. gold and silver bullion smelted for first half of month.

A representative of the state engineer's office has visited the camp, securing data and inspecting proposed hydro-electric sites. As all these power installations are under the jurisdiction of the state, this move is thought to augur favorably for an early realization of adequate and cheaper power for the district.

OREGON.

Sumpter.

The Cougar mine has been purchased by the United Gold Mining Co., Spokane, and operations will be resumed by Nov. 15. C. C. Robins, secretary-treasurer, says that the old mill is being remodeled and a 2½-mile pipe line is being installed to provide water for power and milling, after which production will begin. The plant has a capacity of 125 tons, provided by two 5 by 8-ft. tube mills and five 20-ft. cyanide tanks. This can be expanded to 250 tons by the addition of tube mills and tanks. About \$150,000 had been expended on development and improvement up to the time we bought the property. About 5000 ft. of work had been done, blocking out 100,000 tons of ore having a value of over \$1,000,000. The engineer who supplied these figures took 176 samples and in measuring the total value he eliminated all assay returns above \$20. It has been calculated that 34,000 tons above the 1st and 2nd levels have an average value of \$14. The calculated cost of stoping and milling is \$3. The shoot is continuous for 1100 ft. and has a back of 300 ft. at its interior extremity. Another \$1,000,000 will be added to the resources by driving a tunnel 100 ft. below the upper block if the ore continues. This tunnel is now in 500 ft. The former operators did not make a success, because the concentrating system was not suited. We have had exhaustive tests of different treatment made, and we have discovered that a satisfactory recovery is possible by finer grinding before cyanidation.

Mrs. F. N. Doty, Denver, Colo., purchased the Tempest mine from Millard and E. E. Bennett on Oct. 16. The price was \$50,000, to be made in five semi-annual payments of \$10,000. The mine includes three claims, the Tempest, the Saturday Night and the Seward. It taps the same system of veins as the Ben Harrison, being but a short distance from the latter. It has been operated for 20 years, but no mill has ever been erected. Ore which ran from \$26 to \$32 per ton was sufficiently rich to ship. There are two tunnels on the mine, one 400 ft., the other 500 ft. long. Ore valued at \$75,000 is in sight. Work is to be begun immediately, shipping as much as possible before winter. Plans for the erection of mill and cyanide plant are still to be perfected.

The Taber Fraction and Rastus mining claims have been sold to James A. Howard and associates of Baker by the Taber Fraction Mines Co. for \$60,000. The company's holdings are regarded as the richest for their size in Oregon, and in the 15 years they were operated before litigation caused suspension about 8 years ago, they were credited with earnings of \$250,000. Activity was resumed a few days ago through the workings of the E. & E. mine, adjoining, at a depth of 800 ft. vertical depth in Taber ground. In the early days of the district there were a number of pockets of practically pure gold discovered in the Taber claims, and more than \$100,000 worth of clean, high-grade quartz is said to have been extracted between the surface and the 200 level, while a vein 3 to 8 ft. wide, carrying from \$18 to \$25 a ton in gold, was opened in the lower workings, the lowest of which has a vertical depth of 1100 ft.

SOUTH DAKOTA.

A compressor for drills and other machinery has been installed at the New Golden West and work is progressing under General Manager Williams. The main tunnel is 600 ft. from the portal. It has penetrated the big ledge for 110 ft., and has not as yet reached the foot wall, which is

supposed to be at least another 100 ft. The ore through which this tunnel has been driven is of excellent grade, but the rich part of the ledge, as demonstrated by the holes which had been bored with core drills before the tunnel was started, has not been reached. Several months ago quite a number of these holes had been sent down on various parts of the ledge and from the cores taken out assays of excellent average value were received. It is the intention to cut this section of the ledge from which the rich ores were taken. At 50 ft. from where the tunnel has entered the ledge a station has been cut and a raise to surface started. It is expected this work will take several weeks, as the rock is very hard. This work, however, will not interfere with the driving of the tunnel. Together with this work the plan of blocking out ore will be pressed.

UTAH.

Beaver.

The working shaft at the Hoosier Boy has been completed to the 800 level. They are now drifting from this station to connect with the lead ores which have been opened on the 200, 400 and 600 levels. They have found ore in place in all the workings where drifts have been sent out from the shaft to make connections. It has been a good grade of ore that could be shipped direct to the valley smelters and it is located in a portion of the camp where ledges of lead ore have been found previously. Ore was found on either side of the shaft in two fissures.

The Paloma shaft is down 635 ft. and the 600 level is now being opened. Here high-grade pockets are coming into the drift to the west. This ore resembles that taken out further up the shaft that sampled 44% copper, 43.6 ozs. silver and 11% lead. In new workings 800 ft. to the south of the main shaft a winze sunk on an ore shoot in a fissure is still showing values. Paloma's deeper workings have been in the limestone with the objective the monzonite contact, but now the work is in the monzonite on the 600 and the drift is making for the limestone. On this contact is the most favorable place for the deposition of ore. It is expected to directly prove that these pockets are from feeders sent out from the main ore bodies in the adjacent contact.

Bingham.

With 500,000 shares, par value 10 cts., the Lucky Six Mining Co. was recently formed to operate a property adjoining the Utah Apex, Jay Gould, Alamo and old Quinn. The first vein has been cut in the tunnel. There is now exposed 2 ft. of shipping grade. It samples 5% copper. A drift has followed the ore for 40 ft. This new adit in Cottonwood gulch is in 150 ft. At 200 ft. the second fissure will be crosscut. Drifts will be sent out to where this north-south fissure intercepts the limestone beddings. These are said to be the same as those in the Utah-Apex, where the ore makes.

Eureka.

It is reported that smelting companies, which some time ago notified mine operators that they could not handle the large supply, have relaxed some and notified mine operators that they can now gradually increase their production until normal is reached.

On the 1700 level Iron Blossom is sending a drift toward the new copper deposit from the No. 1, or main workings. It is a long distance between the No. 1 and No. 3 workings and consequently the face of the 1700 drift is still a few hundred feet from its objective point. The fissure is said to carry occasional bunches and stringers of copper ore. Should the deposit be picked up it will mean that Iron Blossom will have several hundred feet of stoping ground as the ore body was first located on the 700 level and later developed on the 1200.

Eagle & Blue Bell shaft is now completed from the 1832 to the 1925 and some ore saved from this work for shipment. On the 1925 the management started a short drift. After it had gone into ore for 20 ft. the work was stopped and sinking resumed. It is thought that the shaft work will not be stopped again until the 2050 level is reached, when drifting

will again be taken up. In the Eagle & Blue Bell mine water will probably be encountered a short distance below the 2050. On the 1875 level some development work has been done from the new shaft. This station was cut in a lean place in the new ore body. Some fair ore appeared at that depth. At this time a drift is being sent out to get under the winze which followed the ore for 100 ft. below the 1700. This winze was in the high-grade ore the entire distance. About 100 ft. of work should take this drift almost directly below the winze and enable the company to make a connection between the drift and winze by raising from the 1875.

Goldhill.

A railroad to be completed in 90 days is being built in to the Deep Creek district by the Utah Construction Co. It is causing considerable activity among the mining properties. The Wilson brothers have a large force of men working on their properties. They are still shipping considerable scheelite ore from the Seminole Copper ground. This ore is going out by parcel post. On the ground owned by Clarence and Ernest Bamberger a rich strike of copper ore was made recently. The extent of the ore has not been determined, but it is declared that there is an entire face of high-grade material.

Midvale.

The plant of the Midvale Minerals Co. has been completed and the first 2 cars have been sent to the sampler. The lead-zinc concentrates will run about 45% zinc. The new plant was built at a cost of \$100,000, and has a capacity of between 300 and 400 tons of tailings per day, handling the lead-zinc dump of the old U. S. smelter at Midvale, of which there is an amount too large to estimate. The oil flotation process is followed in the plant, in which Janney flotation cells are used in separating the lead from zinc. George Sheldon, mining engineer, is president.

Parowan.

A compressor and other machinery is to at once be installed at the Arrowhead leases, the Mines Development Co. having lease No. 3. The work started last July with an 18-in. vein has widened out until now 7 ft. of shipping ore is in sight. This is 65 ft. deep on the incline from which 2 cars of first-class have been shipped, 2 are on the stock pile and it is estimated that 4 more are in sight. Grab samples made from ore broken in the face gave returns of 39 to 42% lead and 4 ozs. silver. With greater depth other workings in the vicinity show that the leaching has stored up steel galena with a much higher silver content. This is the ore zone that it is proposed to prospect with the new compressor plant to be ordered immediately.

WASHINGTON.

North Port.

The Flanigan property is showing up very good and is now owned and operated by the Iroquois Mining Co. The ledge has been traced through two of three claims and where opened contains 3½ ft. of clean ore, besides the carbonates, which make up a total width of 5 ft. The maximum value in lead is 82%, while the average ranges from 65 to 70%. The vein is distinct and follows a lime diabase dike and a lime contact. Opportunities for economical development could hardly be improved upon as may be gathered from the fact that a depth of 300 ft. may be attained by drifting 360 ft.

Spokane.

The Loon Lake Copper Co., which owns and operates the Loon Lake property, 40 miles north of Spokane, in Stevens county, has authorized the expenditure of \$15,000 in further development, according to Frank G. Crane, secretary-treasurer, who states that the work will begin immediately and will be rushed as rapidly as possible. The mine is to be opened to 300 ft. greater depth, and levels will be run each 100 ft. A 50-hp. boiler and engine, to operate the hoist and pumps, now are being installed, together with a compressor and ventilating system. "When receipts for ore already shipped to the smelter are available we will have

ample funds to complete the proposed development," said Crane. "The work probably will begin next week, when we expect to have the new equipment in operation. We have decided on these plans because of the encouraging showings encountered recently on the 200 level, where a shoot 3 to 7 ft. wide and about 160 ft. long has been stoped to a height of 35 ft. The lowest returns we have received on shipments was 11% copper, while the highest has been 13.75% and the average 12%. We have shipped 6 cars to date this month, and another probably will be forwarded soon. With the 2 cars consigned in the last week of September this will make 9 cars that have been delivered to the smelter in 5 weeks."

WISCONSIN-ILLINOIS.

Platteville.

Deliveries of zinc ore for week ending Oct. 28, totaled 129 cars, 5086 tons. Two cars of lead ore cleared, 70 tons; shipments of pyrites were made as follows: Linden Zinc Co. from Linden, 40 tons; from Cuba, 140 tons; National Separators, Cuba, 366 tons; Mineral Point Zinc Co., 339 tons; Monmouth Zinc Mining Co., crude pyrites, 40 tons. The gross recovery of mine run ore for the week was light, 3692 tons being reported. Shipments to smelter direct were also light, 2804 tons.

The base price of blende advanced during the week, going from \$63.50 to \$65 for standard 60% concentrates. The advance in price gave little stimulus to independent producers, few reporting during the week. Local producers were shut out entirely, the East End mine shipping 1 car, 40 tons. Hodge mine to Cuba, 2 cars, 86 tons.

The Wisconsin Zinc Co. is operating at maximum capacity at all points in the field. Dividend No. 3, 2% quarterly, was paid Oct. 28; eight drilling squads are engaged, one each, at the following prospects: Champion, Monroe-Longhorn, Copeland, Winskill and Raisbeck, in New Diggings district; Harris, at Day Siding; South Cottingham, Millbrig; Calvert, in Benton district. Rich strikes are being made daily. The force at the Champion mine has been raised to 100. The range has been proven for 2000 ft., and the Robbins quarter section to the south and east is being developed.

The Federal mine, one of the Wisconsin Zinc Co.'s producers, has run its course. Another, the East End, has been abandoned and the surface rig dismantled. It is being removed to newly developed producers in the Benton district. The Birkbeck mine, Galena district, is producing 35% concentrates from 8% dirt, but a shortage of labor is holding output down to 100 tons weekly. The Longhorn mine is a new producer on which a new rig is nearing completion, and from which service is expected the 15th. The Skinner Magnetic Separating plant at New Diggings is operating three shifts, and handling 130 tons of concentrates daily, giving an average recovery of 70 tons of 59% blende. Further enlargement of the plant is planned, but no official announcement has been made definitely. The Winskill mine, a Wisconsin Zinc Co. mine, is going double shift with 75 men and making 175 tons of concentrates weekly. The C. A. T. mine, another new producer, is running on a range drilled out for 1500 ft. The dirt runs 15% recovery in concentrates. At all of the zinc ore refineries in the field, a market is now offered all low-grade producers. A Whaley electric shovel in operation at the Champion mine is giving satisfaction. Advantage is shown in furnishing dirt to mill on account of shortage in labor. Official announcement is made that a new 200-ton power and concentrating plant will be built in the spring on the Copeland property in the Shullsberg camp. Uniformly rich strikes are now being made on this property with drilling machines.

Benton.

Frontier mining interests took the lead last week on ore deliveries, shipping 12 cars, 480 tons. New Jersey Zinc Co., Fields Mining & Milling Co. and the Champion mine each 7 cars, total 840 tons. Longhenry, Indian Mound, Grand View and Sally mines contributed a total of 55 cars, 4,392,000 lbs. One car of lead ore cleared 40 tons. Benton Roasters,

high grade ore, to Eagle Picher Lead Co. 3 cars, 100 tons; Wisconsin Zinc Co. from Skinner refinery, to Lanyon Zinc Co. 3 cars 123 tons; Sandoval Zinc Co. 32 tons; Eagle-Picher Lead Co. 4 cars 185 tons.

Cuba City.

Improvement is shown here in shipments of high grade. National shipped 5 cars to Illinois Zinc Co. 196 tons; to Granby Con. 6 cars, 233 tons. Linden Zinc Co. to La Salle 3 cars, 105 tons; to Eagle-Picher Lead Co. 3 cars, 100 tons. Standard Metals Co., Chicago, is sending 1 car low grade to Grasselli Chemical Co. 30 tons; 2 cars to Wisconsin Zinc Co. 65 tons. The G. O. P. Mining Co. has taken over the Big Eight mine and proceeding without delay to provide complete mining and milling facilities. The receipts of raw ore at the National Separating Works, last week ran 20 cars, 801 tons.

Mineral Point.

No returns for the Highland district were shown last week. The Linden camp was light on shipments and strong on crude recoveries. Mifflin district shipped 18 cars last week 711 tons. Here the new Senator mine was showing shipments of crude ore in quantity. The Big Tom mine operated by the M. & A. Mining Co. started after extensive development work underground and the completion of a new 200-ton plant. The Peacock Mining Co. an exceptionally heavy dividend payer during 1915 is reporting no dividends at present. The O. P. David mine, at Montfort, operating under the control of the Hump Mining Co. Theo. A. Waech, Supt., is going double shift, with 50 men and making a high grade wet concentrate, assaying 55% zinc. The range mined here for years has veered to the north after trending due east $\frac{1}{2}$ mile. The Mineral Point Public Service Co. is supplying electric power to 20 companies. The total horse power supplied exceeds 4000. A number of new properties are being brought in on the main circuit. The line is now being extended to Cobb and Edmund, two villages on the Northwestern Railway. Receipts of raw ore at the refineries of the New Jersey Zinc Co. were light, only 20 cars coming in for 899 tons. Shipments of high grade finished product to smelter at DePue were 16 cars, 620 tons.

The building of a spur from Strawbridge, a siding on the Galena division of the Northwestern railway, which the officials agreed to put in last spring and which has so far not even been attempted, will be constructed without fail, according to an agreement reached between officials of the New Jersey Zinc Co., Wisconsin Zinc Co. and Vinegar Hill Zinc Co. Other mining corporations deriving benefit from this spur will join in the project. The stub will be 2 miles long, extending to the Skinner Zinc Refinery. A tunnel will be included, 631 ft. long, 14 ft. wide and 20 ft. high. The estimated cost will be about \$80,000. The new outlet will save all the big zinc producers a 4-mile haul overland, and will eliminate hauling ore to and from zinc refinery plants. It is agreed to finish the work of building within 60 days. Incidentally, a most insistent demand from all mining districts to officials of the Northwestern railway that Sunday service be instituted, met with a prompt response, and the service is to be supplied without any delay.

WYOMING.

South Pass.

The Carissa mine, owned by John Spry, Chicago, made a start towards resumption of activities under the management of A. B. Clark, Butte, Mont. Of late Nevada interests have been examining the property with an option to buy. If they do not take the property it will be operated by its owner, with Clark in charge. At present 150 tons of old concentrates that will run around \$125 a ton are being freighted to Lander and shipped. Two cars have been sent out and the rest will be loaded as fast as possible. The present mill will be operated this winter and the work of developing the property continued. Next summer arrangements will be made to increase the capacity of the mill and provide cheaper power. A storage tank for oil which is used in the engines is being built at the mine and everything put in shape for

an all winter's run. While the mill was running this fall the rock averaged around \$40. With high values the property can be operated at a profit despite the cost of power, which is excessive at present owing to lack of fuel.

CANADA.

BRITISH COLUMBIA.

Fairview.

The zinc plant here is being reconstructed to suit the needs of the French Complex Ore Reduction Co. A large electric generator has been ordered from Newport News, Va., and the plant will probably be ready for operation when it arrives. The old roasting furnace has been completely overhauled, a tube mill installed, vats erected and the electrolytic depositing tanks put in place on the site of the old thermo-electric smelting furnace. The cost of reconstruction will not quite reach \$40,000.

Rossland.

An operating profit of about \$10,000 was made by the Le Roi No. 2 mine during August, according to the monthly report, which has just been received from the London office of the company. Shipments of ore totaled 1507 tons. Smelter returns were \$17,380, being payment for 1287 tons. Payment for sundries was \$174, giving a total revenue of \$17,554. Ore production cost \$6000, capital expenditure was \$626, and development, including diamond drilling, was \$7300, making a total of \$7926.

Ashcroft.

President Keffer of the Highland Valley Mining Co. states that a 9-ft. vein has been uncovered at surface. "Returns on the first carload showed a content of 9.6% copper and brought \$1088. The mill, to have a capacity of 55 to 75 tons, will be ready for a trial run within less than a month. Continuance of the surface showings has been proved in part by a tunnel that has attained the 250-ft. point and a depth of 100 ft., where the ore has a width of 8 $\frac{1}{2}$ ft. Also, it is being proved by a raise near the face of the tunnel and another raise 200 ft. back, which will be used for glory hole operating, and by a winze. The tunnel will be continued 600 ft. Tests have shown an average content of 6%. Twenty thousand tons of ore are available by calculation. Three stringers of good ore have been encountered in driving a tunnel 110 ft. in the Sanson group and while the ore is good the bodies are not large enough to be of value. The Sanson group adjoins and is part of the Highland Valley property, comprised of 11 claims under bond and four we have located."

ONTARIO.

Cobalt.

The Jackson & Jackson interests, Buffalo, N. Y., consist of some 50 properties in both the gold and silver areas of northern Ontario. These have all recently been consolidated. At present all are in the prospect stage.

A drift on the 500 level of Temiskaming shows a 2-in. vein of 5000 oz. ore. The vein has widened out to 5 ins. and the ore is equally rich. An end of a blind, unused drift on the 500 level has been walled off and this place is the storage vault for high-grade. At the present time there is approximately \$100,000 worth of silver in large slabs ready for shipment, stored there.

Raising on the shaft at the Adanac has been completed and the shaft completed to the 325 level. Sinking will be taken taken up immediately to the 425 level. At 408 a level will be established leaving the remaining depth for a sump. When the station is completed a crosscut will be pushed to cut the veins to the west and east, where patches of silver were found on upper levels. This will take exploration down nearer the contact and to a point where the chances of finding ore bodies of some importance are believed more favorable.

At the Peoples mine drifting was recently resumed and the first vein was cut after about 38 ft. of crosscutting on the lower level along the contact. It is being drifted on now while at the same time the crosscut is being continued to cut another vein about 40 ft. ahead.

World's Index of Current Literature

A Weekly Classified Index to Current Periodical and other Literature, Appearing the World Over Relative to Mining, Mining Engineering, Metallurgy and Related Industries, in Four Parts.

Part 1. *Geology*—(a) Geology; (b) Ore Genesis; (c) Mineralogy.

Part 2. *Ores and Metals*—(a) Metals and Metal Ores; (b) Non-Metals.

Part 3. *Technology*—(a) Mines and Mining; (b) Mill and Milling; (c) Chemistry and Assaying; (d) Metallurgy; (e) Power and Machinery.

Part 4. *General Miscellany* (including Testing, Metallurgy, Waste, Law, Legislation, Taxation, Conservation, Government Ownership, History, Mining Schools and Societies, Financial, etc.

Articles mentioned will be supplied to subscribers of Mining and Engineering World and others at the prices quoted. Two-cent stamps will be received for amounts under

\$1. Subscribers will be allowed a discount of 5 cts. if the price of the article exceeds 50 cts. The entries show:

(1) The author of the article.

(2) A dash if the name is not apparent.

(3) The title, in italics, of the article or book. Titles in foreign languages are ordinarily followed by a translation or explanation in English.

(4) When the original title is insufficient a brief amplification is added. This addition is in brackets.

(5) The journal in which the article appeared; also the date of issue, and the page on which the article begins.

(6) Number of pages. Illustrated articles are indicated by an asterisk (*).

(7) The price.

I. GEOLOGY

GEOLOGY AND MINERALOGY

Geology

Bancroft, J. Austen.—*Mining Operations in Quebec During 1915*. [A separate report on the geology of the zinc-lead deposits in Portneuf county is included].—Quebec Dept. of Mines; Report; pp 146*.

Barnett, V. H.—*Geology of the Hound Creek District of the Great Falls Coal Field, Cascade County, Montana*. [Geologic maps and description of the formation are given].—U. S. G. S. Bull. 641-H; pp 17*.

Boulton, W. S.—*Geology and Petroleum Resources*. [Abstract from the presidential address to the Geological Section of the British Assn.].—Petro. World Oct. 1916; p 489; pp 2¼; 35c.

English, Walter A.—*Geology and Oil Prospects of Cuyuna Valley, California*. [On the geological structure with respect to oil possibilities].—U. S. G. S. Bull. 621-M; pp 25*.

Ferguson, David.—*Form and Structure of the Coal Fields of Scotland*. [A paper read before the Inst. of Mg. Eng., England].—Coll'y Guard, Sept. 22 1916; p 545; pp 1½; 35c.

Ferguson, Henry G.—*The Golden Arrow, Clifford and Ellendale Districts, Nye County, Nevada*. [Description of the geology and what little work has been done in the field].—U. S. G. S. Bull. 640-F; pp 11*.

Difference in domestic and foreign prices explained by the fact that the New York quotations are per fine ounce; the London per standard ounce 8.925 fine.

Copper.—Business to a large volume has been done in copper since our last report. Producers and dealers alike state that demand has been very active and buying by both foreign and domestic consumers shows no signs of receding. The situation in copper is unprecedented. Producers have become accustomed to heavy production and consumption, but the fact that a copper buying movement which had its inception early in August still continues brisk as the month of November opens is something without a parallel in the industry. Business is of a nature that indicates the uncovered position of many consumers. Although for many weeks it was assumed that domestic consumers would not be so foolhardy as to allow their requirements over the first quarter of next year to go unprotected, it has been ascertained that several wire drawers and brass makers, all large consumers of copper, have only in the past week bought metal for their December and January requirements and declined to buy beyond the latter month, despite the urgent warnings of the producers. Foreign business has also been very brisk. An inquiry coming from French buyers for 100,000,000 lbs. has been the dominant development. While some well-informed copper factors have been inclined to disbelieve that such an inquiry exists, adequate proof as to its authenticity has been seen. That the allied countries should be in the market for so large an amount after having purchased the enormous total of 448,000,000 lbs. is proof of the greater copper consumption abroad. The new inquiry calls for delivery beginning November, but as these terms are impossible for producers to meet, negotiations are now under way to have the prospective buyers accept later delivery.

Should expansion in refining capacity enable an output of 200,000,000 lbs. a month by January it is likely that some producers will have a few million pounds of copper in excess of their sales. It is observed that producers have not sold up to the full prospective output as the danger of refinery yield not increasing sufficiently still exists. It is estimated that sales already made for delivery in the first half of next year involve fully 80% of the copper that will be produced and with quite a number of consumers adhering to the old policy of covering needs only two months ahead it is manifest that whatever copper remains unsold, or may be produced in excess of expectations, will readily find a market.

The situation in copper exports is peculiar. Since Oct. 1

and up to Oct. 30 exports of only 27,309 tons have been reported from New York, Philadelphia and Baltimore, the three leading ports. Predictions were that exports in the last 5 months of the year would run above 35,000 tons a month, so, therefore, the small shipments in September and also the month just closed are not readily understandable.

A slight easing up in electrolytic at London has been noted since our last report. Standard futures also moved off. However, as the London market is only a nominal affair, subject to government control, the changes fail to exert any repressive influence here.

Quotations for copper per pound at New York for the week ended Nov. 1 were as follows:

Tin.—Buying of tin futures has been very active in the past week, tin plate makers being in the market and taking good amounts for delivery up to and including June. Covering of requirements has followed the filling up of order books of tin plate makers. There still remains a sizable business to be done, but with the east advancing the limits on the active absorption here buyers have temporarily withdrawn from the market. The spot position is very strong and holders are waiting for the October statistics before offering. Other consumers of tin were not in the market to any great extent, but it is expected that when the statistics are announced that buying will be more spread out. Spot Straits tin advanced steadily, touching 42 cts., a price that was predicted early in the month. Spot Banka sold at 41¼ cts. On Oct. 1 spot holdings amounted to 3100 tons and it is stated that on Nov. 1 less than 1500 tons tin will be in store here. Arrivals on the Atlantic coast since the first of the month total only 2655 tons and with the country consuming close to 4000 tons a month it is inevitable that spot holdings diminish. Shipments from the Straits are also expected to fall off. Limits from the east for February, March and April shipments were at 40¼@40½ cts. Straits tin for November delivery sold up to 41½ cts. and as November opened was held at 42 cts. For December delivery sellers did business at 41¼ cts., with January, February and March arrival sold at 41½ cts. London and Singapore have acted irregularly since our last report, but withal prices showed some gains.

Quotations for tin per pound at New York and per ton at London and Singapore for the week ended Nov. 1 were as follows:

	New York		London, Straits, spot.	Singapore, shipments.

Lead.—Demand has been of fair proportions, but there has been nothing in the way of unusual developments. The market has held strong at all times, due to the well sold up condition of producers and the lack of metal in the hands of dealers. The A. S. & R. Co. has adhered to its quotations of 7 cts. New York and 6.92½ cts. St. Louis, much to the surprise of trade factors, who over the entire month were expecting a change. It is stated, however, that these prices were not applied to all business and that many consumers were unable to secure metal at all from the principal producer. Independents are not very anxious to sell for November delivery, having disposed of the bulk of the output for this month, and indications are that a premium market will soon be in full swing. Spot lead was held at 7.20 cts. New York and 7 cts. St. Louis in the outside market. Independents quoted November and December delivery at 7.05 cts. New York and 6.95 cts. St. Louis, but at this writing no business for November can be done at these prices. From a news standpoint the lead situation has little of value, as the conditions obtaining have been detailed here previously. Since Oct. 13 the London market has held unchanged at £30 10s for prompts and £29 10s for futures, a situation that will probably be explained in the mail advices due late this week.

Quotations for lead per pound at New York and per ton at London for the week ended Nov. 1 were as follows:

	New York			London	
	Indpts.	A. S. & R. Co.	Spot.	Spot.	Futures.

Lead Ore.—Little change was noted in the market of the Missouri-Kansas-Oklahoma district during the week ended Oct. 28. It was firm and prices ranged from \$80 to \$87 as during the previous week. The production for the week of 2,656,855 lbs. was nearly 1,000,000 lbs. more than during the previous week. The total for the year to that date was 86,169,302 lbs., these amounts having respective values of \$13,456 and \$3,571,877.

Zinc Ore.—The market during the week was stronger than for some time past and there was a raise in prices, especially during the latter part of the week, when from \$67 to \$75.50 was obtained for ores. The week's production was 18,240,330 lbs. and the total for the year 419,617,820 lbs., which amounts were valued at \$436,286 and \$23,098,824.

Calamine.—The Granby camp in the Missouri-Kansas-Oklahoma district had an exceedingly large production. In all other respects conditions were about the same as during the previous week and prices ranged from \$35 to \$45. There were 4,177,940 lbs. of concentrates produced, making the total for the year 29,889,385 lbs. The value of the week's production was \$83,901 and the year's to date \$919,625.

Spelter.—After galvanizing interests had covered their requirements of spelter over the first quarter of next year, the market subsided, both in activity and prices. As soon as business fell off sellers began to offer at concessions. The variations in spelter are being studied with more than usual interest. It is noted that with the advent of demand the price advances quickly and quite sharply, but following the suspension of buying the reaction is just as rapid and as sharp. Producers disclaim partaking in the fluctuations, asserting that they are holding to their established quotations.

It is noted that dealers are the chief seekers of business and that the lowest quotations are obtainable from them. Spot prime western is now quoted at 10.20 cts. New York and 10 cts. St. Louis, while for first quarter sellers are offering at 9½ cts. and would probably shade to 9¼ cts. on firm offers. Producers report that some important brass makers are shortly to enter the market. Some galvanizers have again been nibbling, but the prices they offered did not attract sellers. Brass special has held steady at 10¼@11 cts. St. Louis for spot. At London the market has had a reaction, carrying spot down to £53 5s and futures to £50 15s.

Quotations for spelter per pound at New York and per ton at London for the week ended Nov. 1 were as follows:

	New York		London	
	Spot	Futures	Spot	Futures
Oct. 26	10.30	£54 0 0	£51 0 0	51 0 0

MISCELLANEOUS METALS.

Quicksilver.—Business in quicksilver has been limited with the market holding strong and unchanged at \$80 per flask for spot virgin metal. Sellers report that supplies are none too plentiful, with buying fairly steady. Investigation developed the fact that sellers are not so optimistic as to further price advances. Generally it appears that quicksilver has been pegged at \$80 per flask, a price that sellers and producers are pleased to obtain.

Manganese Ore.—The situation in Cuba respecting manganese ore is similar to that obtaining with tungsten ore producers. High prices months ago induced holders of low-grade properties to begin operations, with the result that the demand was satiated. Prices receded and the lower level of earnings are insufficient for many operators. Latest advices from Cuba state that quite a number of the mines are being closed and that many operators will sustain considerable losses. The demand for manganese ore has been very dull. Sellers here report that no business at all has been taken in the past month. Cuban ore, 40% metal contents, is quoted at 55@60 cts. per unit. Some sellers quote chemical ore at 3½ cts., but others are asking 4½ cts.

Antimony.—The market has again become soft, due to the absence of business. Spot supplies are scarce, but sellers are freely offering December metal. With consumers well covered, the spot scarcity is of little benefit to producers. Spot antimony is quoted at 12 cts. in bond, but some Chinese sellers are asking 12½@13½ cts. duty paid New York. There have been some Russian and Italian inquiries in the market, but nothing has been done on them.

Tungsten.—A sizable business in tungsten has been done during the month of October. The earlier reports of inactivity were obtained from interests who were handling the product of producers who have been holding for more money. Sales of about 450 tons were closed during October at prices ranging from \$16 to \$17 per unit. Quite a little foreign ore figured in the transactions. This week tungsten ores were advanced to \$18 a unit for high-grade containing

very little phosphorus, with other grades quoted at \$17. The Atolia Mining Co., whose plant has been closed for some time past, is expected to resume operations in the near future. Most of the business done has been for spot delivery, but some sizable orders for delivery over all of next year have been booked.

Aluminum.—Sellers report the market as being quiet without any change in the general situation. Prompt virgin ingots are quoted at 64@66 cts., with No. 1 remelted at 60@62 cts. and No. 12 alloy at 47@49 cts. No. 1 virgin ingots for 1917 delivery on contracts are quoted at 35 cts.

No. 20. Vol. 45.

CHICAGO

November 11, 1916.

Alaska Has One Up-to-Date Flotation Plant—the Kennecott

HENRICUS J. STANDER.

The writer recently visited the various mining camps at different points in southeastern Alaska. To the mining engineer the chief points of interest in this territory are Treadwell, Thane, Juneau, Cordova, Kennecott, Valdez, Ellamar and Latouche. The workings at the camps around the Juneau bay, namely the Treadwell group, the Gastineau at Thane and the Alaska Gold, certainly impress the outsider with the fact that Alaska is more up-to-date than many people believe. That splendid and extremely modern mill of the Gastineau at Thane will indeed remove any doubt that one may have with regard to southeastern Alaska. Here, however, we do not find any flotation.

With the exception of the work that is being done by the Kennecott Copper Corporation at Latouche, there is as yet no flotation plants in operation in this territory. The Kennecott Copper Corporation has its workings both at Kennecott and at Latouche, but it is only at the latter place that the company carries on flotation work. We are all familiar with that rich high-grade copper ore that this company is shipping from Kennecott, but there are many of us, I feel sure, that are not acquainted with the excellent flotation work this company is doing at Latouche. This property at Latouche was formerly known as the Beatson mines.

The Latouche plant is under the very able management of E. T. Stannard, and the flotation section of the plant has a capacity of 600 tons of ore a day. While I was there, however, they were busy rebuilding, and their capacity will soon be 1000 tons of ore a day by flotation treatment.

The ore as it comes to the flotation machines, assays as follows:

- 2.20% copper sulphide.
- 9.60% iron sulphide.
- 7.0 % magnesia.
- 9.21% aluminum oxide.
- 4.69% sulphur.
- 1.06% lime.
- 63.43% silica.

The above is a fair average of the daily composition of the ore. And from these figures one would conclude that certain obstacles would be encountered when one tries to obtain a very clean copper sulphide

concentrate. Such is actually the case. The old-type Janney machines are used, and the plant consists of two separate units. Over 90% of the concentrates are taken off by the two head cells respectively.

There are two great obstacles that trouble this company more than they do most, if not all, other flotation operators. These are, firstly, the very heavy freight rate from the plant to the smelter on the concentrates. The Latouche concentrates are to be shipped from the plant to the smelter at Tacoma. Secondly, the steamboat companies refuse to carry concentrates unless they contain moisture below a stipulated amount. This action was taken by the navigation companies, after one boat was lost, due to the fact that a heavy cargo of wet concentrates had shifted. The captains of the Alaskan boats will all tell you that it is impossible to keep an even keel when the boat is loaded with wet concentrates.

This makes it necessary at Latouche to produce as clean a concentrate as is absolutely possible, regardless perhaps of the percentage of recovery, and then to get this concentrate as dry as possible. For the drying process it has been found that the Oliver filter is not enough, but the concentrates after they come from the filter, have to pass through a heating process.

It is the general practice in the United States to think primarily how good a recovery is being made by the flotation process; in other words, almost the first thing we think of is how low the tails run, after they emerge from the flotation machines. The percentage of metal in the concentrates, of course, plays a very important part in all flotation plants; but I feel confident in saying, after having seen almost all the flotation mills in the United States and Canada, that the prime consideration of the flotation operator is that, how low he has succeeded in reducing the sulphide in the tailings. A low tails effects the percentage of recovery proportionately more than a high-grade concentrate. So that when one tries to increase the percentage of metal in the concentrates, one usually decreases the percentage of recovery. At the Latouche plant it is necessary, because of the above-mentioned

two reasons, to give first consideration to the percentage of copper sulphide in the concentrates.

With a view to obtaining a clean high-grade concentrate, this company has done some remarkable work during the past year. No acid is used, and they have not yet decided whether the results obtained with a hot pulp are better than those obtained when the pulp is treated without heating. In the oil mixture they have found that they obtain best results when 60% of steam-distilled pine oil is mixed with 40% of a collecting oil mixture, made up of fuel oil and coal tar.

To show what good results they are getting, the ore as it comes to the flotation machines, runs on an average 2.3% copper; the concentrates assay from 17 to 18.5% copper; while the tails run about 0.28 to 0.3% copper. Anyone familiar with the usual practice in flotation will admit, from these figures, that what little work is being done by the flotation process in Alaska, it ranks fairly high in efficiency, when compared with the flotation work in the west generally.

Many men in the other camps in southeastern Alaska have expressed the opinion to me that it will not be very long before we will hear about some more flotation plants being constructed in that territory.

Decreasing Ore Waste in Metal Mining

E. T. LEDNUM.

In the winning of ores from their natural beds by blasting, physically fine flaky material is not desired and is a source of serious loss to mine operators. Nevertheless metal mining companies are generally disposed to use the higher grade explosives, perhaps overlooking the economical requirements of a blasting explosive.

With the exception of iron, manganese and a few other base minerals, ores which are crushed and concentrated for their metallic values should not be pulverized or shattered to flaky or powdery fines.

The speed of detonation (that is, the speed of action) of the explosive in the drill hole is in proportion to the volume of gas and heat developed in a given time. These are established facts.

High-grade, quick-acting explosives break down the mineral into minute particles, especially in the zone adjacent to the explosive charged surfaces in the drilled hole. There is also no doubt a fusing effect exerted on zinc ores and other easily reducible ores from the softer rocks. This action is decided, especially where holes are drilled and charged in the ore bodies proper.

Explosives exert the disruptive, crushing and disintegrating effect throughout the burden in direct ratio to the action of the explosive. Low-grade, slower-acting explosives will not be as severe, or produce proportionately the resultant physically fine ore from the blasted burden, as will the higher grades and quicker acting explosives. It will be necessary to do

more boulder blasting when using low-grade explosives if the explosive charge in the drilled hole is not sufficiently tamped with "stemming." Dynamite in a drilled hole without "stemming," when exploded, will exert a great deal of its force on the material which holds it, but as the effect of the explosive is in line of the least resistance, the natural result is that the charge in an untamped hole will expend a great part of its energy in blowing back out of the hole. Explosive charges should, therefore, be "stemmed." The reason for this is set forth in the formula:

$$P V = R T$$

in which P = Pressure and V = Volume; R a constant for each Gas and T = Absolute Temperature. If Temperature remains the same, no matter how Pressure or Volume vary individually, their product will be equal to the constant R T. If Temperature increases and remains constant, R being already constant, nothing is left but for Pressure to increase in the same ratio as Temperature, and the resultant efficiency of the explosive is increased, as will be shown by the quality of the work done. The quality of mine air will also be much better after the blast.

All boulders should be block holed to reduce vibrations in the mines with consequent bad results. However, there would be much less finely divided material left in the mine, and the ore would go to the mill in better condition to be broken down from hard masses, permitting the mill to perform its proper functions; and less finely divided particles of mineral would be carried off in the sludge water and tailings.

The conservative use of explosives adapted to the winning of ores from their bed will not only prevent losses in transportation—that is, from the ore body to the smelter—but will effect further economies in the installation of elaborate flotation and other concentrating equipments to secure the finely divided mineral particles.

Powdered minerals cannot be satisfactorily separated by gravity and as it is therefore important in designing crushing plants to so construct them to minimize as far as possible the sliming of the minerals, the minerals should not be so produced by blasting in the first winning from their deposits.

Japan as a Source of Tungsten.—Exports of tungsten ore from Japan in 1915 were 85 tons to the United States, 214 tons to France, and 110 tons to the United Kingdom, or 409 tons in all. Estimated shipments to July 20, 1916, are placed at 480 tons, most of it going to the United States. The tungsten output of Japan is reported as 25 to 40 tons of ore per month from the Kiwada mine, 10 to 11 tons per month from the Takitori mine, and 75 tons per month from several small mines. Those in Corea produce between 50 and 60 tons per month. Attempts were made to obtain tungsten from Siam, but the ore contained large percentages of tin, greatly reducing the value.

Safety in Hoisting and Slope Haulage

O. P. HOOD.*

The practice of mining usually requires transportation of men and material in both horizontal and vertical directions. Man has pretty thoroughly accustomed himself to the means of horizontal transportation and the risks of the road and the car are assumed naturally and without fear. Transportation in vertical directions, however, is far less ancient and universal in the experience of mankind and the dread and fear of falling is a primal instinct yielding but slowly to the experience of successful vertical transportation. That man by a universal experience in aerial transportation is to finally become so familiar with the possibility of falling from great heights, that he will assume the risks of the road with the same equanimity as we now cross a crowded thoroughfare or take the night express, may be a possibility, but at present there is an instinctive fear accompanying the lifting and lowering of men that is not present when transportation is in horizontal directions. A man who would never think of examining the coupling arrangements of a railroad train looks with suspicion on the $1\frac{1}{2}$ in. steel rope that is to lower his 170 lbs. of self a few hundred feet into a mine.

Safety in hoisting, as in most other activities, is dependent upon both men and mechanism. The division of the responsibility between these two is the object of this paper. The Bureau of Mines will issue shortly a study by R. H. Kudlich of shaft and slope accidents that have taken place in the coal mines of Pennsylvania, West Virginia, Ohio, and Illinois in the 10-year period from 1904 to 1913. In this safety field, as in most others, the human factor is the main factor. If man had succeeded in controlling himself as well as he has succeeded so far in controlling the mechanism of hoisting, shaft and slope accidents would have been one-third less. Of 1726 accidents, 800 are so reported as to make it possible to locate the blame as between men or mechanism. Of these 800 accidents, 66% were due to human limitations and 34% to some failure of mechanism. In 35% of the accidents the victim was himself responsible. It can be said that of three men injured in these accidents, one had himself only to blame, one suffered because of the failure of a fellow employe, and one suffered because of defective mechanism. The miner, therefore, who is using, or who is about the hoisting facilities of a mine, is equally interested in three factors: First, his own carefulness; second, the carefulness and ability of his mates and, third, the adequacy of the company's equipment. The company interested in reducing shaft and slope accidents will find that there is twice as much need for revision of the habits,

thoughts, and practices of the men as there is of making any change in the equipment.

The kind of accidents in which the injured man is himself more largely responsible are those such as the 10% injured in falling down the shaft; the $6\frac{1}{2}$ % caught between the cage and shaft timbers; the 5% who fell off cages while riding and the 5% struck by slope or haulage ropes. The remedy for these accidents must be found in the general propaganda which teaches men to think safety, together with the elimination of the habitually careless and of those conditions which produce mental and physical subnormality.

Accidents for which a fellow employe is more largely responsible are those such as the 13% caught in overwinding accidents and the 7% injured by being struck by or while riding on runaway cars.

To entirely prevent these accidents requires infallible humanity or the development of accessory mechanism that will prevent the individual from doing the wrong thing and will supplement his ineffective effort. Here again the individual must be at his best physically and mentally. Anything which helps to produce a subnormal condition in a faithful and intelligent employe should receive careful study and be eliminated if possible. This leads the investigator into every field affecting the individual, health, wages, housing, normal pleasures, decent living, diet, the prohibition of artificial stimulants and drugs, etc., etc. It may be too much to hope to produce ideal men and conditions, but it is necessary to face the fact that these human problems are the big end of the problem. Overwinding devices are needed that are reliable and practical and that will not interfere with normal operation. Too often the devices provided are ineffective or disconnected. In large hoists some of them may when operated even wreck the mechanism. Standard recording signal systems should be developed so that misunderstanding of signals will be next to impossible, and a permanent record made of the signals as given.

The kind of accidents where the mechanism is largely at fault are such accidents as runaway cars on slopes, accounting for 9% of the injuries; breaking of ropes, $7\frac{1}{2}$ %; being struck by slope or haulage ropes, $4\frac{1}{2}$ %. Most of these accidents are on slopes. Twenty-five per cent of accidents on slopes or haulage ways are charged to failure of equipment, while in shaft accidents less than 9% are so chargeable. This is probably due to the more severe conditions imposed on slope and haulage ropes, and to the absence of means on slopes of something comparable to safety catches in vertical hoists. To reduce accidents from defective mechanism requires first of all frequent, careful, orderly and formal inspection of all mechanism

*Chief Mechanical Engineer, Bureau of Mines; published by permission of Director Bureau of Mines.

and, second, the development of standards of condition that can be imparted by one to another. This latter need becomes very evident to any one attempting to obtain from practical men about a mine definite directions for condemning a hoisting rope. The practice in this respect is arbitrary and variable, and only once in my experience have I heard directions so clearly given that an intelligent assistant could inspect a rope and report whether it should or should not come off.

In attempting to reduce shaft and slope accidents it is useful to know the major problems which should demand first and greatest attention. These are shown to be human problems first and can be summed up in the phrase "keeping good men fit." The problems of mechanism are more largely matters of efficient inspection rather than of design or material, although these latter factors are strong minor subjects.

Portable Acetylene Gas Generator.

Oxy-acetylene flame apparatus for cutting and welding is coming to be a necessity around mines. The acetylene gas used in the operation is ordinarily obtained in tanks, under high pressure, which of

PORTABLE ACETYLENE GAS GENERATOR.

course lends a certain element of uncertainty, since, through carelessness, the supply of gas may run out before a new tank is obtained.

To be able to generate the gas on the spot to operate the torch is, therefore, an advantage and a simple

type of apparatus is shown in the drawing, being the invention of Prior F. Willis, St. Louis.

The lower part of the generator contains water, which may be replenished and the sludge drawn off through suitable valve arrangements. Into this water small charges of calcium carbide are automatically dropped, from time to time, out of the container in the top. The carbide, combining with the water, produces the acetylene gas.

To start the operation of the carbide feeding device, the valve rod (21) is dropped by hand to its lowest position, whereby any carbide in the space within the ring (19) will drop into the water. The gas generated will then fill the tank and carbide receptacle, and flow through pipe (26) into the regulator at the top.

If the gas pressure is sufficient to raise the regulator to its highest position, the cone (23) on the end of the valve rod will engage the ring (24) and under side of the flange (19) and close the bottom opening in the carbide receptacle. At the same time the valve (20) will be raised clear of its seat, and carbide will slide down the sides of the container (16) and fill the space within the ring (24) and flange (19).

If the pressure of the gas is insufficient to raise the regulator, the latter must be raised by hand, and then dropped to feed a second charge of carbide into the tank. Hand feeding must be continued until sufficient gas is evolved to raise the regulator to its highest point, after which the operation is automatic.

The regulator will remain in its highest position until the consumption of gas has reduced its pressure sufficiently to let the regulator fall, which allows another charge of carbide to fall into the water, and this operation takes place over and over.

Water Power in Southeastern Alaska.

The streams of Alaska have been important factors in its industrial growth. The success of placer mining in northern and central Alaska has depended primarily on the water available for hydraulicking and dredging, and in southeastern Alaska water power has long been used by mines, canneries, sawmills, and other industries, although until recently most of the plants have been small. Since 1906 the Survey has been making systematic studies. Lack of definite information in regard to the quantity of water available and other physical factors that determine the feasibility of a power site has been one of the principal impediments to development. For this reason a systematic investigation designed to determine the location of feasible water-power sites in southeastern Alaska was undertaken. As an outcome of this later study a report, prepared by G. H. Canfield, entitled "Water-Power." Investigation in southeastern Alaska has been recently published as part of Bulletin 642.

Operations and Methods in Use at the Inspiration Property, Arizona*

The ore in the Inspiration property occurs as disseminated chalcocite in silicified schist and granite porphyry, approximately 90% being in schist. The ore body of which the Inspiration holdings are a part extends from its eastern limits in Miami Co.'s ground to its western limits in the Inspiration-Live Oak ground, a distance of 9700 ft. The ore is continuous for this distance, except where the Keystone ore is parted from the Inspiration ore for a horizontal distance of 1100 ft., due to the movement along the incline of the Bulldog fault. The ore varies in width in

there will have to be driven 13 ft. of ordinary sized drifts, 20 ft. of main raises and 1.4 ft. of haulage ways, making a charge for this account of approximately 20 cts. per ton of ore mined.

For the 5 months' period ending with August, there were mined 18.1 tons for each shift's work above and below surface properly chargeable to the mining department.

Ore Crushing and Grinding.

The mine run ore is crushed first in gyratory

GENERAL MAP OF THE INSPIRATION PROPERTY, ARIZONA.

Inspiration ground from 200 to 1600 ft. and has an average vertical dimension of approximately 150 ft.

Previous to the beginning of stoping in July, 1915, the ore had been developed by 29 $\frac{1}{3}$ miles of churn drill holes and opened up by underground work as follows:

- 1.2 miles of shafts.
- 7.7 miles of haulage ways.
- 21.1 miles of ordinary sized drifts.
- 21.2 miles of main raises.
- 2.5 miles of "finger" raises.
- 53.7 miles total.

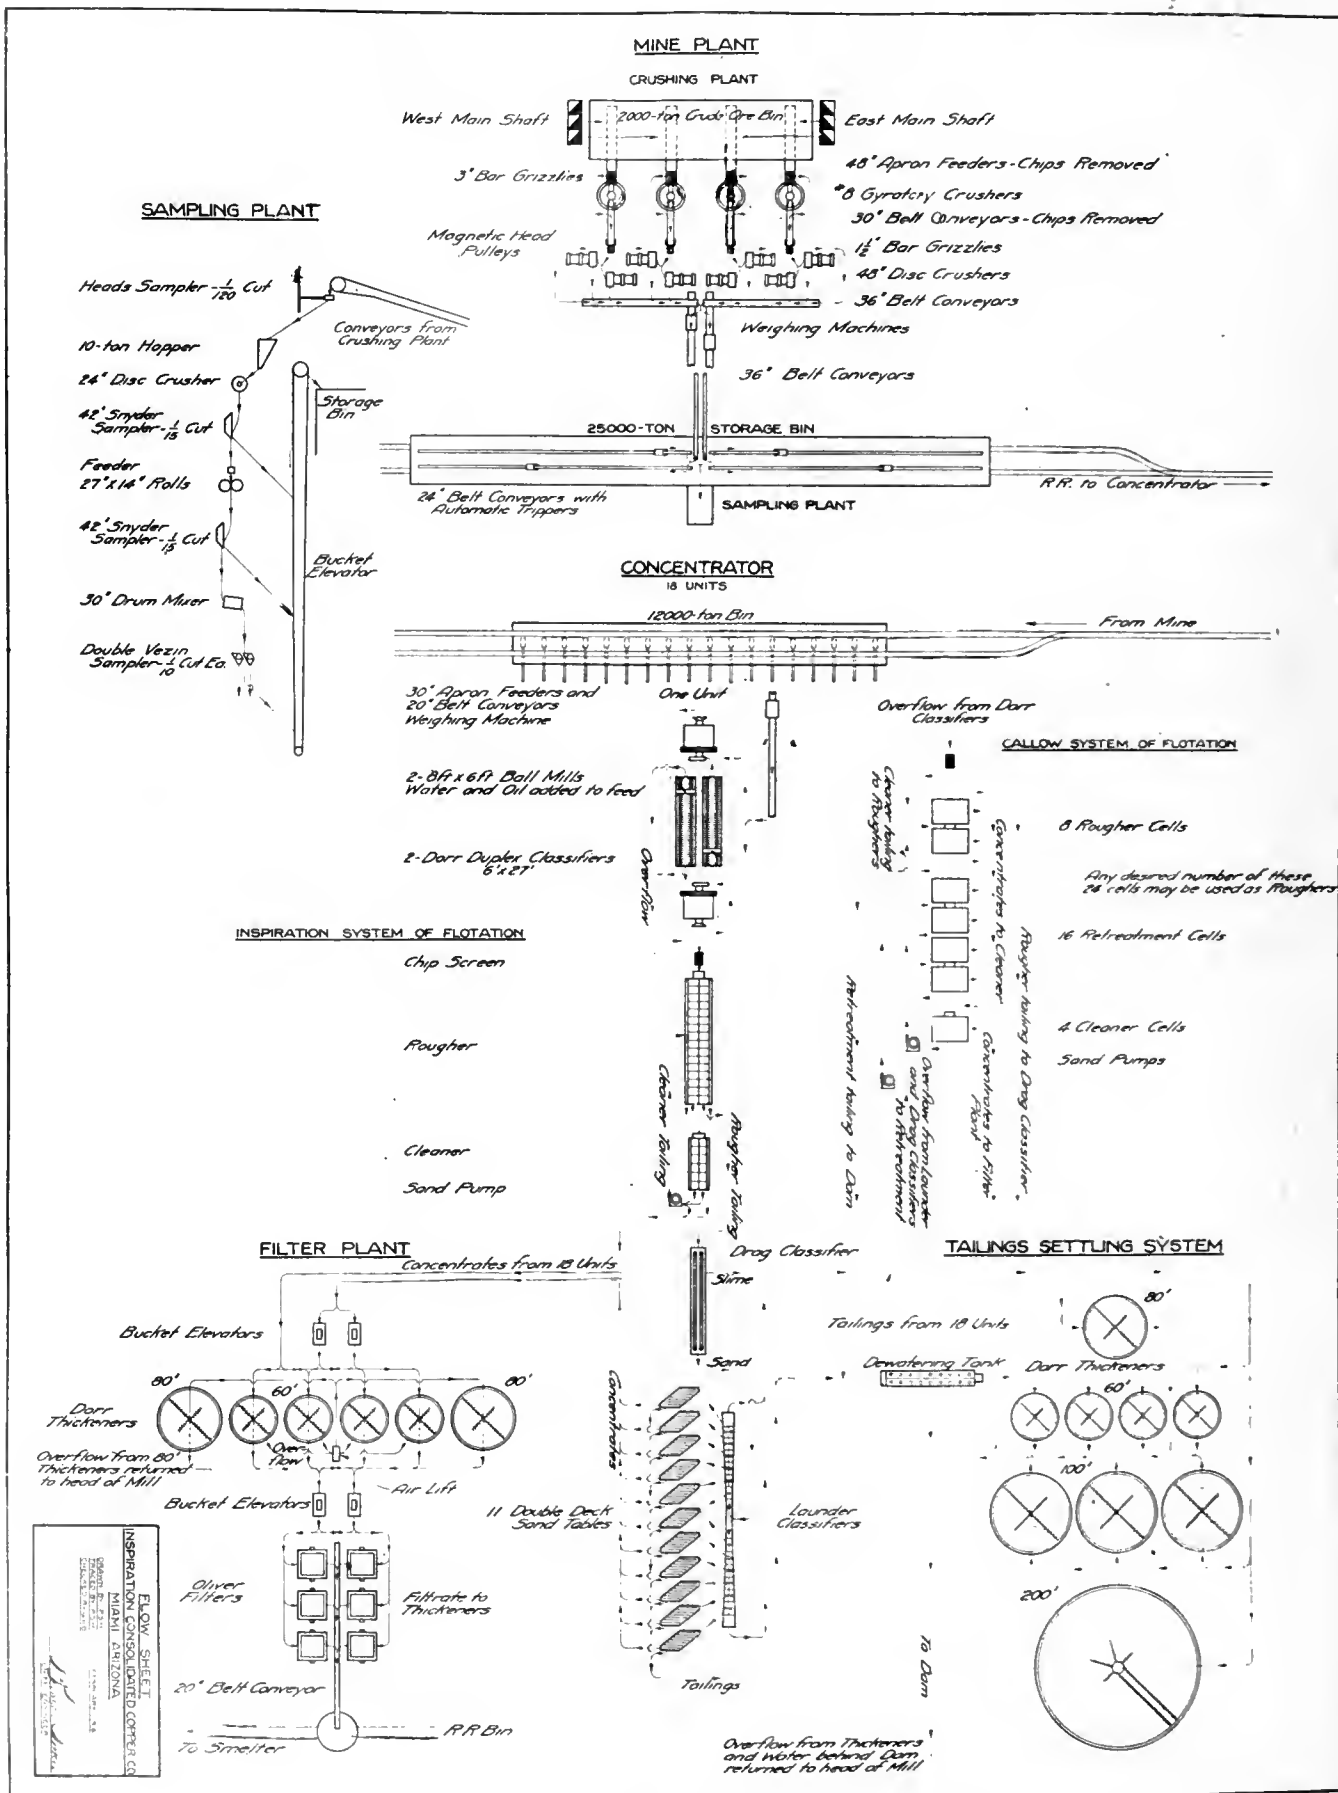

The mining system consists of undercutting and thus caving the ore, which is then drawn off through a system of inclined raises to the haulage ways below. It is estimated that for each 1000 tons of ore mined

*We are indebted to Rudolph Gahl, Metallurgist in Charge of Concentrator, Inspiration Con. Copper Co., Miami, Ariz., for the information contained herein.

crushers having a maximum opening for discharge of 3 $\frac{1}{4}$ ins.—this product passes through Symons disc grinders having a discharge opening of 1 $\frac{1}{2}$ ins. This product is finished in Marcy ball mills at the concentrator, as per the table following:

Preparation of Industrial Minerals.

McGowan, Hill & Mathewson are operating a plant in Los Angeles, Cal., preparing for the market certain industrial minerals, including pulverized silica, feldspar, pumice, talc, flint, fluor spar, barytes and magnesite. They have deposits of pumice in Inyo county, silica in Riverside county, and obtain these other materials in various places on the Southwest desert. Their plant is equipped with a crusher, three elevators, a pulverizer, several vibrating screens and a tube mill. The noteworthy part of the equipment is the Marks centrifugal impact pulverizer, which is operated at a speed of 2000 rpm., and which has handled 2½ tons per hour of 40-mesh material, reducing it to 100 mesh. The latter product is reduced to flour fineness of about 200-mesh in a tube mill.

The Marks pulverizer is not a grinder, the hard material, such as quartz and feldspar, being pulverized by attrition, due to being thrown by centrifugal force from a central rotary disc against the corrugated white iron lining of the cast-iron housing. The high speed and unusual capacity are maintained with practically no vibration of the iron housing or contiguous parts. This machine, made in Los Angeles by D. O. Marks and associates, is being introduced in ore milling.

A Modern English Colliery Chain Drive

This chain drive to haulage gear at Pease's West Colliery, shown in illustration, was developed at the Burnage Works of Hans Renold, Ltd., at Didsbury, Manchester, Eng. This drive with several other 150-hp. drives is installed at Pease's West Colliery at Crook, Co. Durham.

Originally a 150-hp. drive was designed to be used in connection with a 150-hp. electric motor, but when this particular drive was put into service it was found that it was subject to very frequent overloads of as much as 200%. Naturally the engineer felt rather nervous as to the result, but it ran for about a year and a half when, owing to the overloads, the motor began to develop serious trouble. It was then decided

created a demand for a higher, more durable and more accurate type of chain altogether.

These driving chains for collieries consist of three main types, the silent chain, the bush roller chain and the block chain. The silent chain is for high-speed driving and ranges from 1/2-in. wide, with a breaking strength of 1900 lbs. It is capable of transmitting 3/4 hp. at about 1750 rpm. (17,000 pinion) up to 1 3/4-in. pitch, 12.2-in. wide, with a breaking strength 107,100 lbs. while transmitting 140 to 150 hp. at 450 to 500 rpm. (17-tooth pinion).

Power up to about 300 hp. may be transmitted by using more than one strand of chain. The silent is no doubt the most interesting of all driving chains,

THE 250-HP. RENOLD CHAIN DRIVE TO HAULAGE GEAR IN ENGLAND.

to install a motor on more generous lines, and one capable of handling 250-hp. with ease was ultimately chosen. The life of the chain is unduly shortened with wheels above 100 T, owing to the comparative rapidity with which it wears out of pitch with the large wheel, 3% of wear is permissible with a wheel of 100 T. In this case, however, a chain was chosen similar to that being used on other drives at the colliery, so that though it might have worn out of mesh with a 143 T wheel, it could be used up in single strands on 150-hp. drives with wheels of from 90 to 100 T.

Chains of one kind or another have been for many years past extensively used in colliery work, especially for driving screens, tipplers and washing plant. The kind of chain most commonly in use for these purposes has, up till comparatively lately, been principally of the malleable or cast link pattern. Modern "speeding up" tendencies, however, have latterly

owing to its unique design and action. The link comes into engagement without any rolling or sliding, simply shutting down flat against the wheel tooth. As by this time it is traveling practically at the same angular velocity as the wheel tooth, the action is very quiet. In addition to this, the almost frictionless engagement gives the chain an exceptionally high efficiency, about 98% being obtained. The chain remains silent and equally efficient until worn out, since, when wear occurs at the joints, the links simply gear a little further out on the teeth, but in exactly the same manner as at first. Wear, however, is a very slow process.

Borax is the standard flux for melting bullion as it is in assaying ores. As far as possible, careful melters confine the use of fluxes to borax, because of its rapid liquefaction and protective, rather than corrosive, effect upon the crucible.

Triplex Pumps in the Wisconsin Zinc Mines

One of the large zinc mining companies in Wisconsin, not very long ago, made a radical change in its pumping equipment. All existing pumps in both mines and mill were disposed of. In their places triplex pumps were installed. Then the company officials sat back and checked up the power bills. They found in due course that they were saving over \$1000 per month on power alone. Not only will this saving, in a comparatively short time, pay for the complete installation, but, like interest on a mortgage, it piles up month after month—a handsome sum available for other improvements in the matter of reducing operating expense.

It is significant, also, that other operators in the Wisconsin district have been converted to the triplex pump—to the extent of some 25 installations by a single manufacturer—and most of these companies will vouch for the fact that the saving in power has returned the first cost of the pumps in from 5 to 6 months.

That the triplex pump has not in the past been more extensively employed in mine work, has been due largely to the matter of first cost. And this seems particularly to have been the stumbling block in the case of the zinc mine operator. Until recently the price of spelter has been so low that his margin of profit has been very small. Although the saving in power which more efficient apparatus could make was undoubtedly attractive, the more or less hand-to-mouth existence forced upon him seemed always to set ahead indefinitely any radical changes which meant spending money out of hand.

Conditions have now changed in this field. Prices for spelter have advanced and money is now available for some of the improvements long considered, but never made. At this time, then, new power-saving equipment can well be considered and improvements made if they are ever going to be made.

Look over a number of zinc mine installations of the old order and it will be found that the habit prevails of pumping *all* water to the highest point. No matter if only a small amount is required by the rolls and trommels to have this head; it all goes there. This requires power, and power costs money.

The main power-saving idea is therefore to have the pumps do no more work than is necessary. It is summed up very aptly in these two suggestions by the Aldrich Pump Co.:

(1) Belt from line shaft to triplex pump pulley, and pump the larger amount of water to the top of the jigs only (this head in the Wisconsin field rarely exceeds 27 ft. from pond located outside of mill). This pump usually requires about 12 to 20 hp. according to the size of mill.

(2) Install a small triplex booster pump, and belt from mill line shaft, this pump to handle the small

amount of water required to operate rolls and trommels, usually from 100 to 150 gpm., and heads from 45 to 60 ft. This pump requires never more than $3\frac{1}{2}$ hp. at pump pulley.

This arrangement is coming to be the popular one in the zinc mining field, because the mills are generally driven by an independent motor with underload rating. This motor usually has enough reserve capacity sufficient to drive the triplex pumps.

It is quite often the case that the mine makes enough water to operate the mill. In this case one triplex pump can be made to do two jobs; that is, pump the water out of the mine and at the same time supply it to the mill—one unit for the whole service. By placing a gate valve at the top of the shaft, the mine water can be discharged at this point when the mill is not running.

That the triplex type of pump is wonderfully effi-

ALDRICH TRIPLEX PUMP FOR ZINC MINE, EQUIPPED WITH FAWCUS HERRINGBONE GEARS. CAPACITY 750-GPM. AGAINST 300-FT. HEAD.

cient under the tough conditions of mine service seems to have been proven by numerous specific cases. In one large mine in Missouri, for instance, a triplex was installed, throwing 1900 gpm. at a total working head of 30 ft. It did this on 20 hp. at the pump pulley, a remarkable showing when it is considered that a 75-hp. motor was slightly overloaded in operating a pump previously installed to do the same work.

Chilean nitrate exports to the United States in March, 1916, were 2,338,534 quintals (1 quintal equals 101.4 lbs.), against 1,835,803 in March, 1915, and 1,155,351 in March, 1914. For the 9 months ended March 31, 1916, the exports to the United States were 14,020,225 quintals, against 7,048,848 and 7,544,483 for the same period in 1915 and 1914 respectively. The increase to the United States is therefore about 100% in each case.

Operating Skip Hoist by Alternating Current.

In a furnace or skip hoist, the motor must necessarily be of large size, owing to the very heavy unbalanced load, which load often amounts to several tons. This load must be carefully handled, particularly at or near its limits of travel, so as to insure that the skip will come to rest directly over the furnace bell, in position for dumping, regardless of the load or speed of the motor. This result may be affected more or less satisfactorily when the hoisting motor is a direct-current machine. But where the hoist is to be operated by an alternating current motor, the result is much more difficult to attain.

In slowing down and stopping a direct-current motor the dynamic brake effect supplied by the motor itself is utilized, the motor operating as a dynamo.

OPERATING SKIP HOIST BY ALTERNATING CURRENT.

But with a standard type of alternating current motor, this brake effect is lacking, since such a motor will not act as a self-exciting generator.

In a new type of hoist, a direct-current generator is coupled to an alternating-current hoisting motor. Then this generator is separately excited by current supplied by a motor-generator. The alternating-current hoisting motor is controlled by means of electro-responsive devices operated exclusively by the direct current generated by the two sources above mentioned.

By this method it is possible to control the main motor in accordance with its load and speed, and to overcome the many objectionable features inherent in practically all electro-responsive devices operated by alternating current.

The accompanying illustration shows the general

arrangement of the elements. Those interested in following the electrical switching mechanism and connections will find them disclosed in a patent recently issued to David Lindquist of Yonkers, N. Y.

Good Roads in Arizona.

An important factor in the mining industry that is everywhere apparent in Yavapai county, Arizona, is the system of good roads being established for the purpose of bringing the outlying mines and camps into touch with the county's main business center at Prescott, and with each other. Much has already been accomplished along these lines; and as a result this county can now justly lay claim to some of the best-graded roads in the West. Notably the Copper Basin road which has put that city in easy transit communication with the copper areas of that section; the Groom Creek road which serves a like purpose for the camp of Senator; the Lynx Creek road connecting with the smelter at Humboldt and the mines of that locality, and the Cherry Creek road that gives access to Jerome, Clarkdale and the mines of the Verde valley country. More recently the distance from Prescott to Phoenix has been appreciably shortened by reconstructing the old government trail through Black canyon. This piece of road building has put the Tip Top and other mines of the district in touch with these cities, and has added appreciably to the pleasure of travel by auto as well. The Groom Creek road is being extended beyond Senator to tap the rich mineral-bearing Crown King country and other portions of the Bradshaws, and consideration is being given by the county commissioners to a plan for shortening the road between Prescott and Jerome.

Fluorite.—This mineral, chemically fluoride (Ca F), has been imported into this country principally from Derbyshire, England, where the largest deposits in the world are located, though it is also produced in many districts of the world including Saxony, Germany. In 1910 there were about 42,000 tons imported against 70,000 tons produced. By 1915 the import figure was reduced to 7167 tons with 136,940 tons produced in this country. During 1915 Illinois, Kentucky, New Hampshire, Colorado and New Mexico were the producing states, but recently South Dakota has entered the list. The mineral is used considerably for fluxing in the metallurgical industry, particularly iron and steel. Now that this metal is in exceptional demand so also is fluorite. This, together with the fact that imports from Europe have been cut off, has affected a change in the prevailing price of about \$5.50 for 1915 and the ore is now bringing prices ranging from \$10 to \$12 per ton.

In the treatment of gold from retorts or from precipitates, iron is frequently present in considerable quantities.

The Tonopah Extension Mines in Nevada

W. A. SCOTT.

The main pump station at the Tonopah Extension mines is on the 1540-ft. level at the Victor shaft. The equipment consists of an Aldrich quintiplex 150-gal. pump, and a Gould duplex, 120 gals., both electric driven. These pumps were submerged nearly a year, caused by the opening of a vein on that level which carried a large volume of water, filling the lower workings. It required almost a year to dewater that part of the mine, and this was accomplished by bailing, operating a station pump at the 1200, and by the use of sinkers.

The Victor shaft has been retimbered to the 1540-ft. station, where an electric hoist will be put in position; and soon the work of sinking this shaft 300 to 500 ft. deeper will begin. Three compartments will be maintained as sinking proceeds. An important feature of development lately consisted of sinking a 3-compartment underground incline shaft from the 950 to the 1350-ft. levels. Much of the ore is now brought up this incline to the 950-in., 2-ton, self-dumping skips, which discharge into loading pockets on that level, being used. This incline runs close to the vein on its dip.

Drills used comprise Denver dreadnaughts for cross-cutting and drifting; and for stoping, the valveless Waugh, and Ingersoll-Rand's butterfly type are used. Two underground electric tramways are employed for one haulage—one on the 950 and the other on 1540. The ore is hauled to the shafts in mine cars, in which it is hoisted to the surface. The ore tonnage of the mine is hoisted in about equal quantities from No. 2 shaft and Victor shaft. A trolley line is used for hauling ore from the Victor to the mill. In the haulage line between shaft No. 2 and the mill the current is carried by a third rail, but it is claimed this is unsatisfactory, and that a trolley line will be erected and the third rail dispensed with.

The mill, which takes 300 tons of ore per day, began July 1 to treat all ore by cyanidation, to the exclusion of table concentration. The cyanide treatment is by means of leaching tanks, Trent agitating tanks, Dorr thickeners and Butters filters. The ore from Victor shaft enters the mill in 1½ to 2-in. sizes, that from No. 2 shaft 2 to 3-in. These ores are fed to the ten 5-stamp batteries, having 3-in. screens, and are crushed in cyanide solution. The next step in pulverization is by five tube mills; three of them are 5 by 16 ft., and two are 5 by 18 ft. Each tube is operated by a 50-hp. electric motor, connected thereto by a Morse chain drive. These drives give a positive and steady motion, and are much used on tube mills and mill pumps. In this mill the 25 solution and slime pumps are driven by motors connected to them by Morse chain drives. Some of them used here have been in service 5 years.

The disuse of concentrating tables in this mill may or may not be a permanent change. It is understood

a test is being made with cyanide treatment exclusively. In the meantime, tests by oil flotation are being made in the mill in a 1-ton experimental plant, equipped with Callow cells.

A time-saving device has been produced and put in use at the assay office of this company, where 175 to 180 assays per day are made. It consists of patent moulds used in pouring, the slag being poured from the crucible upon a hot steel plate, and as the metal appears it is poured into a truncated, cylindrical steel mould, 15 of which were made in a steel bar 18 ins. long. It requires some skill in pouring to turn the hot slag in one place and the hot metal, which makes up the button, into another; but by skillful handling the slag is poured separately, and the pure metal turned into the mould. When the 15 moulds are filled, a metal plate is placed on top, as a lid, and the bar containing the moulds is reversed, the clean metallic buttons dropping out. They are now ready for cupellation. The process dispenses with the pounding of the buttons to free them from slag. This device was the joint invention of Wharton Anderson and W. B. Roundree of Tonopah Extension assay office, the latter being chief chemist. They state that this method has been checked up on control assays and found to have no defects.

Dredge with Track-Section Carrier.

When a dredge is operated from a track, which is moved along ahead of it in sections as the work progresses, considerable hard work and delay are encountered in carrying these sections forward from the rear. This may be lightened by the track-carrier arrangement here shown. On each side of the dredge

DREDGE WITH TRACK CARRIER.

frame, just above the wheels, are two pairs of I-beams (3) projecting somewhat to the front and rear, as shown in the plan view. On these beams travel a little carriage (8) shown in detail. This carriage carries the table (12). In moving a track section forward, all that is necessary to do is to lift one end and place it on the carriage, pushing it along the front of the dredge.

A Portable Vertical Electric Air Compressor.

Illustration shows a novel vertical electric air compressor. This high-speed vertical compressor is a simple, practical and economical machine. It has an enclosed crank-case, keeping out the dust and dirt and automatic splash lubrication, so perfect that not a grease cup, oil cup, or oil hole is necessary. There are no stuffing boxes nor cross-heads and the light sheet-steel valves are said to be practically indestructible, seating without any wear on the cylinders, insuring noiseless operation and the valves are of large

PORTABLE ELECTRIC AIR COMPRESSOR.

areas and very flexible. It has small floor space mounted on a steel frame with four wheels. There are few parts and absence of intricate mechanism which makes it ideal for places where the best mechanical skill is not available. The compressor's light weight makes it particularly desirable for portable units, the high speeds permitting the use of high-speed motors on these combination units.

Multiple Hearth Furnace for Treating Lead Matte.

Roasting lead matte in a single hearth furnace is an operation easily performed, but wasteful of fuel. To do the roasting in a multiple hearth furnace is more economical, and many forms of such furnaces have been tried. But there is one objection which has arisen in using the multiple, superimposed type. The gases accumulate heat as they pass in succession over the superimposed hearths, and as a consequence the upper chambers reach such a high temperature that the

incoming supply of matte soon becomes so sticky that it cannot be stirred or moved over the hearth by the rables.

Utley Wedge, of Ardmore, Pa., has devised a furnace in which he is able to maintain a lower temperature in the upper portion than in the lower. The matte passes downward from chamber to chamber in the usual way, and the temperature in the different chambers is maintained just sufficient to effect the desired sulphide elimination, but not high enough to effect sintering, or cause the matte to become sticky.

Heat is applied directly in the lower portion of the

MULTIPLE HEARTH FURNACE FOR TREATING LEAD MATTE.

Wedge furnace, where a high temperature is necessary to carry the elimination of sulphur from the calcine to the desired point; and then, instead of allowing all of the hot gases to pass through the chambers above in series, part is permitted to escape. This is effected preferably from several regulable outlets in each of the chambers, so that the higher fuel economy may be attained by using all of the heat that can safely be used in the lower portion of the furnace, applying the same to the upper treating chambers of the furnace but abstracting such portion as may be necessary to avoid reaching the sticky or sintering temperature in any chamber of the furnace.

Anode mud obtained in the electrolytic refining of copper is treated for the recovery of silver and gold.

Refining Copper from a Cupola Furnace.

In the refining of impure copper such as blister, black, cement, scrap, etc., it would simplify the operation to be able to use a cupola furnace operating on regulated quantities of a given charge. In this way the operation of oxidizing, or flapping, to produce set copper, could be rendered easier and under more perfect control.

Ulysses A. Garred, New York, describes a copper refining apparatus which he has designed along these lines. By means of this apparatus he is able to get away from wood poling, substituting blast poling, and giving better permeation of the reducing agents through the bath, and reducing the time required.

Side and end views of the apparatus are shown in the diagram. An ordinary cupola furnace is shown, which is provided with a chambered offset opposite the spout. Into this, offset fuel (pulverized coal) is sprayed from a nozzle, this being accomplished by

REFINING FROM A CUPOLA FURNACE.

pumping air through the nozzle in the manner usual in coal burners of this type.

This same air system is continued by a pipe down into the poling furnace (F), so that sprays of fuel may be discharged into them. These furnaces are of the rotary or tilting type, with the usual pouring spout. One furnace discharges while the other is poling or blowing, the poled copper being poured into a launder (L).

As the charge in the cupola settles down past the offset chamber, the pulverized fuel projected from the nozzle and previously ignited, impinges against the bottom portions of the descending column of copper, the flaming particles and highly heated products of combustion melting the charge, which settles on the hearth. The air supplied to the nozzle is so regulated as to bring about the necessary flapping or oxidation of the melted portions of the charge.

From the launder (12) the copper runs into the receptacle of either one of the other of the poling furnaces. The temperature in the poling furnace is maintained sufficiently high to keep the copper in a molten or fluid condition, this temperature being brought

about by the burning of the powdered fuel. Should the charge in the poling furnace require flapping or further oxidation before it is subjected to the blast poling, this can be accomplished by blowing air through the nozzles (15) beneath the charge. The metal being in condition for final poling, the operator directs hydro-carbon or equivalent reducing gas under pressure from the pipes (23) at the same time feeding a proper complement of powdered charcoal. The charcoal laden gas is thus forced beneath and through the molten charge, the level of which is indicated by the dotted line (x) in the right hand furnace, and every particle of oxidized copper is thus reached and reduced to the metallic state.

Argonaut Co.'s Tailings Dam.

The new \$25,000 mill-tailings impounding dam of the Argonaut Mining Co., Jackson, Calif., has been completed. It will be put in use as soon as the new 60-stamp mill has been completed.

The dam is one of the largest of its type in the state. It is 500 ft. in length, 40 ft. high and has 13

THE ARGONAUT TAILINGS DAM.

arches. Tons of old hoisting cable were used in reinforcing the concrete. It is of the Eastwood arch type and at its present height will back up tailings of the 60-stamp mill for 25 years. Water will be backed up a half mile.

The dam is of such construction that it will stand an additional raise of 30 ft. when needed. It was constructed by Eastwood Bros. of Los Angeles, Calif., with F. Livingston in charge.

No branch of metallurgy has in recent years received more attention than the concentration of copper ores, nor has results to investigators yielded more satisfactory returns.

The supply of selenium is obtained almost wholly from reworking the residues of electrolytic copper plants and the flue dust in sulphuric acid chambers.

What the Mining Companies are Doing

The Porphyry Copper Production.

The production of the porphyry copper companies in September, comparing with previous months, is given in the following table:

October		5,894,441	3,278,348	4,871,566
November		5,576,083	3,196,457	4,900,994
December		5,725,009	3,126,538	5,232,167

North Butte Co., Mont.

The report of the North Butte Mining Co. for the quarter ended Sept. 30, 1916, shows a production of 5,953,685 lbs. of copper, 247,833 ozs. of silver and 402 ozs. of gold.

Surplus and reserve Sept. 30, 1916, was \$4,789,369, compared with \$4,524,445 on June 30, 1916, and \$3,882,417 on Jan. 1, 1916.

We compare copper, silver and gold production as follows:

Quarter end.	Tons ore treated.	Copper, lbs.	Silver, oz.	Gold, oz.
Sept. 30, 1916.	124,488	5,953,685	247,833	402
June 30, 1916.	146,190	6,074,742	264,400	442
Sept. 30, 1915.	123,500	5,672,890	265,855	305
June 30, 1915.	87,000	4,490,324	239,512	270
March, 1916.	131,071	5,740,193	244,976	385
Dec. 31, 1915.	113,000	5,713,743	256,695	365
Total, 1915	377,500	19,234,969	941,630	1,120
Total, 1914	337,415	18,421,761	1,092,300	1,167

During the quarter ended Sept. 30, North Butte development work totaled 5562 ft.

The features of the development have been the proving of the eastward extension of the ore body on the 2200 level of the North Berlin vein, the finding of ore on the 1800 level

on the same vein, and the cutting of ore on the 2000 level of the Adirondack vein.

A plant has been installed and active development of the East Side properties has commenced.

Shattuck-Arizona Co., Ariz.

The following is a summary of mine and smelter production and costs of the Shattuck-Arizona Copper Co. for the quarter ending Sept. 30, 1916:

	Copper Ore.	Lead Ore.
Dry tons mined	43,818	2,757
Dry tons shipped	43,951	2,467
Dry tons smelted	44,013	2,162
Pounds copper recovered	4,663,466	
Ounces gold recovered	1,243	
Ounces silver recovered	79,995	
Pounds lead recovered	661,034	
Net operating cost per pound of copper	9.05 cts.	
General office expense and taxes paid	.15 cts.	
Total net cost per pound refined copper	9.20 cts.	

Earnings for the quarter are as follows:

Gross value of ores	\$1,274,126.74
Miscellaneous receipts	672.02
Interest received	1,091.46
Operating expense	\$527,778.30
General office expense and taxes paid	6,914.38
Net earnings	\$ 741,197.54
Rate per share per year	8.47
Rate per share per year for year to date	8.43
Total net earnings for the 9 months ending Sept. 30, 1916	\$2,212,000.00

During the quarter, dividends amounting to 12½% were paid, as follows:

No. 16—July 20, 1916	\$175,000
No. 4—July 20, 1916	262,500

Wellington Mines Co., Colo.

The company reports for the 6 months ending May 31, as follows:

Concentrate sales—Zinc	\$507,559.38
Concentrate sales—Lead	20,723.73
Interest earned	1,436.70
Transfer fees	36.07
Gross income	\$529,755.88
Mining, milling and other operating expenses	116,421.06
Net income	\$413,334.82
Balance on hand Dec. 1, 1915	105,943.36
Dividend paid March 15, 1916	\$200,000.00
Dividend paid July 1, 1916	200,000.00
	\$119,278.18
Depreciation reserve	\$ 23,014.55
Surplus	50,000.00
Tax fund	2,500.00
	\$ 75,514.55
	\$ 43,763.63

Granby Consolidated.

From its two smelters at Anvox and Grand Forks there was produced in September by the Granby Con. Copper Mining Co. a total of 3,440,035 pounds of copper.

A comparison of Granby's production for the first 9 months of the past 3 years follows (pounds):

	1916.	1915.	1914.
January	3,122,879	2,170,139	1,793,840
February	2,690,265	1,793,373	1,661,212
March	3,555,411	2,793,692	1,775,852
April	3,950,469	3,071,337	2,132,869
May	4,727,929	3,684,115	2,443,294
June	4,011,361	3,625,322	2,706,595
July	4,258,846	3,889,397	2,214,089
August	3,218,847		
September	3,440,035	4,119,387	

The Granby Co. has been experiencing a bit of hard luck during the past 2 months as shown by production of

less than 3,500,000 lbs. in each of these periods as compared with better than 4,000,000 lbs. each for the 3 months immediately preceding. There was insufficient fuel for a time at Grand Forks by reason of a strike at the source of supply, while local difficulties accounted for the falling off at Anyox. Output by months follows (pounds):

	September.	August.	July.	June.	May.
Anyox	2,180,476	2,394,890	3,092,274	2,799,540	3,383,230
Grand Forks...	1,259,559	823,957	1,176,572	1,211,821	1,344,699
Total	3,440,035	3,218,847	4,268,846	4,011,361	4,727,929

Chief Con. Mining Co., Utah.

The following report of the company's operations for the 9 months of 1916, ending Sept. 30, has been issued:

	Feet.
Drifting	15,791.3
Raises	1,566.0
Shaft	593.0
Total	17,950.3

The total shipments of ore were 62,006 tons, yielding net, after the payment of smelting, transportation and sampling charges, \$1,153,000.83.

Metal contents:	
Gold, ozs.	6,461
Silver, ozs.	1,321,966
Lead, lbs.	13,549,935
Copper, lbs.	1,795
Zinc, lbs.	730,249
Assay values:	
Gold, ozs. per ton	104
Silver, ozs. per ton	21.37
Lead (on lead ores), % per ton	13.08
Copper (on copper ores), % per ton	1.95
Zinc (on zinc ores), % per ton	30.5
Average gross value per ton	\$31.38
Smelting, freight, sampling, etc.	12.78
Average net value	18.60

The net profit after the payment of all charges was \$474,247.35.

Disbursements were as follows:

Operating costs	\$ 502,141.70
Machinery and equipment	11,274.14
Construction	14,135.06
Mining claims	153,594.97
Houghton expense	2,664.63
Dividend No. 7	44,033.80
Dividend No. 8	44,148.15
Dividend No. 9	44,149.55
Due for labor	52,112.33
Oct. 1, 1916, balance cash on hand	446,970.07
	\$1,315,224.40

Big Cottonwood Con. Co., Utah.

The balance sheet of the company as of Sept. 30, 1916, shows as follows:

ASSETS.	
Fixed Assets—	
Mining claims	\$300,500.00
Compressor plant	2,407.38
Powder magazine	25.05
Sundry mine buildings	897.88
Miscellaneous mine equipment	449.37
Small tools	183.02
Mess and bunk house equipment	141.67
Office furniture and fixtures	6.00
	\$304,610.37
Current Assets	
Cash on hand and in bank	\$ 1,701.03
Accounts receivable	10.11
	1,711.14
Deferred charges to operations—	
Exploration	\$ 5,156.73
Promotion and organization expenses	2,538.50
General and administrative expense	896.77
Victor tunnel excavation	11,763.32
	20,355.32
Suspense	778.36
Total assets	\$327,455.19

CAPITAL AND LIABILITIES.

Capital stock issued and outstanding—1,000,000 shares	\$250,000.00
Donated working capital	\$100,000.00
Less discount on treasury stock	36,228.87
	63,771.13
Capital derived from stock assessments	6,875.26
	LIABILITIES.
Notes payable	\$ 5,000.00
Accounts payable	1,808.80
	6,808.80
Total capital and liabilities	\$327,455.19

Miscellaneous Company Reports.

The Franklin Mining Co. produced 740,000 lbs. of mineral during October, against 479,000 lbs. in October, 1915, and 636,000 in September, 1916, and 710,000 in August of this year.

Referee in bankruptcy, Stanley W. Dexter, has ruled that stockholders' protective committee, represented by the North American Liquidation Co., shall be permitted to redeem and take over property and estate of Ohio Copper Mining Co. Trustee's deed will be delivered to committee after court fixes amount due. Hearing has been fixed for Nov. 13. Unsecured creditors are to be paid in full.

We are advised by the Consolidated Mining & Smelting Co. of Canada that directors of the company have ordered an increase in the share capital by one-quarter. Mining operations are being extended and will be further extended. An option has been taken on a copper property on Vancouver Island and other properties are being examined. Each shareholder as of Oct. 21st may subscribe at par for one share for every four shares held.

October production of the Shannon Copper Co., 757,000 lbs., was an increase of about 13,000 lbs. over September, but both months were considerably below normal. August was 925,000 lbs. and July 968,000. In May production got up to over 1,000,000 lbs. The reduced output in October is accounted for by the fact that the furnaces were operated only 25½ days. They were forced to close down on the 13th for 4½ days, owing to the flood in the Clifton district. In September also some trouble was experienced with furnaces because of leaky jackets.

At the Granby Con. property operations are back to normal, a condition, however, which should be more fully reflected in November than in the October results. The August and September copper yield dropped below the 4,000,000-lb. mark. A strike at the Crow's Nest Pass coal property, in which Granby owns a minority interest, during the summer months created a fuel shortage at Granby which made full operations impossible. This situation has improved with the result that both Anyox and Grand Forks smelters have again been tuned up to top speed.

The Greene-Cananea Copper Co. will have distributed \$8 per share to its stockholders during 1916, with the payment next month of another \$2 dividend. Taxes and super-taxes have been levied upon mining companies, which now operate in Mexico, to such an extent that under what were once normal copper prices profitable operations could not now be conducted. The extraordinary levies imposed on Greene's copper production amount to fully 3 cts. a pound indicating an average cost of production of close to 13 cts. a pound. Despite this cost Greene must be showing profits of about \$700,000 per month.

With the consummation of plans, now under consideration, the Miami Copper Co. will during the coming year get its productive capacity up to 75,000,000 pounds per annum. The 1916 output will run between 50,000,000 and 55,000,000 lbs. turned out at an average cost of not far from 9½ cts. a pound. The new production will come from a combination of improvements and enlargements at the mill and mine. The mill capacity will probably be increased through the addition of another section or two, for which provision was made in the original layout. Metallurgical improvements will also play an important part in increasing production.

The American Zinc, Lead & Smelting Co. will, without doubt, report earnings of over \$9,000,000 in 1916. This, of course, includes profits from the recently acquired Granby property. This is equivalent to \$45 per share on the common, after \$6 is paid on 80,000 shares of preferred outstanding. At the present time the company is earning about \$500,000 net a month. Prime western spelter is selling for about 10¼ cts. a pound, and on the company's high grade Mascot prices range all the way from 14 to 20 cts. a pound. On the basis of monthly profits of \$500,000, or \$6,000,000 a year, American Zinc common is today earning \$30 per share on its 193,000 common shares.

Copper Reaching Toward Higher Prices.

The real bull market in copper has arrived. During the entire period of extreme activity in the red metal the upward course of prices was conservative. Now with the clearing up of the odds and ends, with consumers who have been dilatory, seeking to cover, a premium market for copper is rapidly developing. A sale of 1,000,000 lbs. of December copper has been made at 30 cts. Sales of spot electrolytic have been made at 31 cts. For the first quarter of next year business has been closed at 29½ cts. and for the second quarter at 29 cts. Casting copper has advanced to 29½ cts. for spot and 29 cts. for December, Lake copper is practically unobtainable. Throughout the copper market is difficult to quote. Prices on all deliveries up to the end of the first half are subject entirely to negotiations.

The upward movement in prices since our last market report has been sharp. The end is not yet in sight. The interruption to trade caused by election day did not stop the reaching towards higher grounds. Copper is rapidly shaping into a runaway market. Business has been tremendous.

The insistent and large demand for nearby copper is proof of the statement made in our market reports that numerous domestic consumers failed to protect requirements. Since our last report dealers and producers have sold fully 150,000,000 lbs. of copper. Nearby metal prices give promise of attaining levels predicted by leading authorities. It is stated that spot copper will sell above 35 cts. by the end of the first quarter. Dealers who held large lines of spot metal at 30 cts. found buyers extremely desirous of taking over this metal and while a considerable amount of this speculative copper has been sold it is ascertained that dealers still retain control of sizable blocks of the red metal. A million pound lot of February copper sold at 29¼ cts. Several half million pound orders for March were closed at 29 cts. With producers almost entirely cleaned out of first quarter metal the dealers are beginning to reap the harvest.

A Resourceful Mine Manager.

If the history of the prospector, and of that class of canny individuals always on the job where a good lease is to be had, is ever written, it will be sadly incomplete if not replete with the stories of many ingenious makeshifts. To get the ore out at the least possible cost, with the utmost speed and leave the property opened up in a workmanlike manner, such necessity is often the mother of invention.

In Utah there has been formed a corporation that has for its purpose the leasing, bonding and operating of blocks of ground or entire properties. It is known as the Mines Development Co., is a close corporation

and has no stock for sale. Perhaps the following is one reason:

Its manager is a man whose life to date has been spent in prospecting and leasing. Recently the company took a bond and lease covering a period of 3 years on four claims located 25 miles from Lund, Utah. The group is in an unorganized mining district with all that that implies.

Before leaving Salt Lake City for the property the manager ordered a hoist shipped to the property, and was informed that he would get the same according to schedule. At the property a few days later the teamsters delivering supplies gave the manager a message informing him that it would be impossible to deliver the hoist for at least 2 months. There were the usual excuses, but what raised misgivings in the manager's mind was a note added by the secretary to the effect that all of the machinery houses were behind on orders and that the outlook was dark.

After thinking it over the manager decided that a whim was entirely too slow, the haul from the railroad meant high prices for horse feed if he installed the old type of whim—he was right then having his troubles getting hauling done—and for awhile he was in a quandary. The principal value in the ore was lead and lead might begin to drop in price at any time.

And then he thought of the automobile. So he immediately started building a roadway from the shaft. When it was leveled up he attached the cable to the rear end of the automobile, passed it under a sheave wheel at the collar of the shaft, over the sheave wheel at the top of the headframe and down the shaft where the bucket was attached.

It does the hoisting in a rapid and efficient manner at a very small cost, and he is getting out the ore faster, he says, than he could by hoisting it.

Chemists to Supply Urgent Need of Nitrates.

Of all chemical products the nitrates are undoubtedly the most important to our country's welfare and prosperity. Not only do the nitrates form a most essential constituent of fertilizers but in all explosives and gun powders nitrates and compounds derived therefrom form the basic principle. Were we entirely deprived of nitrates, ammonia and other nitrogen complexes not only would our country be absolutely defenseless, but our crops would suffer and our people would undergo a slow process of starvation.

For years we have been depending upon Chili for the supply of nitrates (Chili saltpeter), but the deposits are calculated not to last more than 50 years at the present rapid rate of consumption. And if by some hostile power the importation of Chili saltpeter were entirely cut off, our country would be placed in a very embarrassing situation.

Electro chemists, foreseeing a possible calamity of

this kind, have come to the country's rescue. It is well known that our atmosphere contains 80% nitrogen gas and the problem was to transform this inert and practically useless gas into valuable compounds such as nitrates and ammonia. Our country may be justly proud of the fact that the first plant for the manufacture of nitrates was erected here at Niagara Falls. With the aid of electricity the nitrogen of the atmosphere was chemically "fixed" into compounds to be used in fertilizers and gun powder.

Going to the Mining Congress?

This year try not to miss the things you had particularly wanted to see. You've done it before, because you were rushed, and didn't have a set plan.

There are going to be new things among the manufacturers' exhibits.

Post yourself in advance on the ones you want to be sure to see and study.

The place where you will find this advance information is in last week's issue.

It was out thus far in advance so that you can go through its advertising pages, leisurely; now, while at your desk.

And as you are doing it, make memorandums of the things you really mustn't miss. You'll see them there, and you will find them exhibited at the Congress, or at least men will be there who can tell you all about them.

Pencil and pad; that's the idea.

The war tax on Canadian mines will cost the industry of that country a considerable sum of money, based on the taxes fixed by the Canadian government against the Dome Mines Co. For the period ending March 31, 1916, this company has been called on to pay the government \$27,502. This is at the rate of a little less than 7 cts. a share. When the announcement of a war tax was made in February, the stocks of nearly all Canadian companies dropped heavily, Dome shareholders suffering a loss of about \$6 a share, or nearly \$2,500,000 in value. The tax affects all companies in Canada having capital in excess of \$50,000 or over and demands 25% of profits over 7%. In the case of precious metal mines the capital is computed on the basis of 5 years' profits, and that depreciation at the rate of 10% a year will be allowed. This is to be deducted from the yearly profits before allowing the 25% tax on excess profits.

Producing nowadays at a rate of 1,000,000 lbs. of copper a day, Anaconda Copper Co. enjoys the distinction of being the world's largest copper producer. The main consideration these days has been to get out as much copper as possible with but little effort being made to lower production costs. With costs of producing around 11 cts. the company is earning, basing production on 300,000,000 lbs. annually and a 25 ct. market, no less than \$18 per share annually. Out of this dividends of \$8 per share are being paid.

PERSONAL.

L. D. Ricketts, mining engineer, New York, is in Butte, Mont.

D. Crevling, mining engineer, New York, is at Prescott, Ariz., examining properties.

Alfred Frank is now in charge of operations at the Butte-Duluth mine, Butte, Mont.

Theodore J. Hoover, mining and metallurgical engineer, London, E. C., is in New York.

Edward Durham is superintendent of construction for the Mammoth Copper Co., Kennett, Calif.

Frank R. Corwin has been made assistant superintendent of the International smelter at Miami, Ariz.

J. Parke Channing, consulting engineer, New York, has been in Spokane, Wash., and left for Butte, Mont.

Forbes Rickard, mining engineer, Denver, Colo., has returned from Arizona and left for Lovelock, Nev.

George Nordquist, Chicago, is in Salt Lake City, Utah, and has been examining properties in Beaver county, Utah.

H. W. Aldrich has been made superintendent of the blast furnace and briquetting plants of the Anaconda Copper Co.

Pope Yeatman, consulting mining engineer, New York, is in Salt Lake City, from which place he will return to New York.

Fred W. Bradley, president of the Bunker Hill Mining & Concentrating Co., has returned to Kellogg, Idaho, from San Francisco.

H. B. Paull of New York, auditor for the Calumet & Arizona Co., is now at the main office of the company at Calumet, Mich.

Harry Vivian of the Calumet & Hecla engineering staff, accompanied by Mrs. Vivian, is making a trip to Warren and other Arizona points.

W. W. Wishon has been appointed consulting engineer for the Big Casino Mining Co., of Philadelphia, Pa., with mines near Searchlight, Nev.

Henry V. Snell, general manager of the Warrior Copper Co., Globe, Ariz., has been made general manager of the Miami Copper Co., Miami, Ariz.

Robert A. Brown, former superintendent of the Centennial-Eureka Co.'s mines, has resigned to become superintendent for the Alta Con. Co., Alta, Utah.

F. K. Brunton, formerly with the American Smelting & Refining Co. at Garfield, Utah, is now assistant superintendent of the Consolidated Arizona Smelting Co., Humboldt, Ariz.

Charles W. Newton, manager of the Consolidated Interstate Callahan Mining Co., Wallace, Idaho, has been appointed by Gov. Alexander, a delegate to the Mining Congress at Chicago from the state of Idaho.

W. J. Roberts, vice president of the Traylor Engineering & Manufacturing Co., Allentown, Pa., who has recovered from an attack of pneumonia, while on a western trip, has returned east. On his arrival in Chicago a couple of weeks ago, he could proceed no farther, and was with relatives during his illness.

Thos. F. Cole is at Calumet, Mich. He has just resigned from the presidency and directorate of the Greene-Cananea Copper Co. and as a director for the Inspiration Con. Copper Co. It is understood that Mr. Cole will gradually retire from active participation in companies with which he has

been identified and will make his home in the west. He still retains the presidency of the North Butte Mining Co.

H. Foster Bain was in Chicago last week on his return from a visit to various mining fields which included the Rand and British Columbia. The announcement is made of his retirement as editor of *The Mining Magazine*, London.

Geo. H. Hawes, who established safety and rescue departments for the Oliver Iron, Calumet & Hecla and other large companies later joined the Bureau of Safety of Chicago and has now opened an office for it at 202 Torrey building, Duluth. From that point he will supervise work for various mining companies that are clients of the Bureau.

OBITUARY.

Edward Meader, an operator in the Mogollon district, New Mexico, died at his home near Silver City, N. M., on Oct. 30, 1916. He was 56 years of age and was born in Missouri. In 1879 he came to New Mexico.

L. C. Stevenson, mining engineer, recently passed away in Baltimore, Md. He was 33 years of age and until recently spent much of his time in the vicinity of Sumpter, Ore. Here he managed the Taber Fraction, Golden Chariot and Buffalo mines during various times and was associated in considerable work with W. W. Elmer, mining engineer. About 1911 he left that district and since then was superintendent for the Virginia-Maryland Coal Co., Newberg, W. Va.

SCHOOLS AND SOCIETIES.

Texas School of Mines.—The buildings of this institution, which is affiliated with the University of Texas, were burned with an estimated loss of \$50,000.

American Chemical Society.—At the meeting of the New York section on Nov. 10 the following papers were on the program: "The General Problem of Public Service Training," by Prof. Chas. A. Beard; "The Status and Compensation of the Chemist in Public Service," by Prof. F. E. Breithut; "The Chemist in Public Service," by Dr. Harvey W. Wiley; "The Chemist in the Service of New York City," by Dr. Otto H. Klein.

COMMUNICATIONS.

Machine Placer Mining.

The Editor:—In your issue of Sept. 16th is an editorial headed "Placer Mining of Today," which "hits the nail on the head."

There are large deposits of gravel where water is scarce but values are good that are receiving no attention for reasons set forth by you.

I have worked a small machine, of my own invention, on gravel in Nevada where I could get but 9 gals. of water per minute for 6 hours per day, and still I washed an average of 32 yds. per shift, 8 hours. I am now operating such a machine in Placer county, California, washing a creek bar—sand and pebbles—at the rate of 10 cu. yds. per hour, using (as per rating of pump by manufacturers) 65 gals. of water per minute.

Possibly this information may be of interest to others of your readers having similar ground.

Rocklin, Cal.

J. B. GIFFEN.

NEW PUBLICATIONS.

Spirit Leveling in New Mexico. By R. B. Marshall. Washington, D. C., U. S. Geological Survey. Bulletin 638; pp 112.

The location and elevation of all the bench marks in the state are given and classified according to the quadrangle in which they are located.

Abstracts of Current Decisions on Mines and Mining. By J. W. Thompson. Washington, D. C., U. S. Bureau of Mines. Bulletin 126; pp 90.

The decisions include those which were reported between January and April, 1916. Legal phraseology is entirely left out, the abstract being simply a description of what the finding of the court with respect to controversies regarding mining laws.

Lime in 1915. By G. F. Loughlin. Washington, D. C., U. S. Geological Survey. Mineral Resources of U. S. II:19; pp 20.

A general review of the industry with respect to the whole United States is first given and includes data on production. Lime as used in different industries is treated separately for each industry and some information is given on the use of fuels in burning lime.

Methods of Sampling Delivered Coal. By George S. Pope. Washington, D. C., U. S. Bureau of Mines. Bulletin 116; pp 64; illustrated.

Details of methods and equipment used in the sampling of delivered coals are given. Different methods of sampling are given for several different classes of sampling and other information bearing on the same is supplemented. Complete details regarding specifications for the purchase of coal for the government are reproduced.

Tin Ore in Northern Lander County, Nevada. By Adolph Knopf. Washington, D. C., U. S. Geological Survey. Bulletin 640-G; pp 14; illustrated.

Wood tin is the form in which the ore is found and though to date the deposits have not been opened to a great extent the nature of the mineral as given in this report would seem to warrant the same. The contents for the greater part is a description of the country and the geology of the formation and deposits.

Bauxite and Aluminum in 1915. By W. C. Phalen. Washington, D. C., U. S. Geological Survey. Mineral Resources of U. S. I:7; pp 16.

Besides reviewing the production and conditions of the industry by states in the United States some space is given to reviewing it in foreign countries. The uses of bauxite are taken up, principal among which is metallic aluminum and other aluminum products. The sources other than bauxite for aluminum are given and a brief is contained on methods of making aluminum from bauxite. The general aluminum market during the year is then discussed and the common uses of the metal given.

Cosna-Novitna and Ruby-Kuskokwim Regions, Alaska. By H. M. Eakin, J. B. Mertie, Jr., and G. L. Harrington. Washington, D. C., U. S. Geological Survey. Bulletin 642-H; pp 56; illustrated.

The first named district to date has not been found of any noted importance so far as gold or other mineral deposits are concerned. It is treated on but briefly principally with respect to the geography of the country, though some information is given on its economic geology. Gold, both placer and vein, is the principal mineral of importance in the other district. The geology and geography of the country is described in general for the entire area and brief separate descriptions are given of operating properties and the smaller sub-districts.

TRADE PUBLICATIONS.

Chain Drives for Power Transmission. Morse Chain Co., Ithaca, N. Y. Publication 14; pp. 20; illustrated.

The chain, its construction and uses are described briefly in detail though for the greater part the publication consists of views showing installations in plants of the company's Chain and each view is accompanied with a short description.

Briquetting, Magnetic Separating and Sintering Equipment. The American Grondal Co., New York. Pamphlets; illustrated.

In these three pamphlets the Grondal briquetting, magnetic separators and concentrates made by Grondal separators sintered by the Greenawalt process are discussed. Each subject is considered in a concise manner with some details.

Machinery for the Mine, Mill and Smelter. The Morse Bros. Machinery and Supply Co., Denver. Catalog; pp. 42.

Every class and kind of machinery used about the mines, mills and smelter for power of all kinds, drilling, concentrating, etc., are included. Each class of equipment is under a separate head and these are included in a well gotten up index in the front pages. This catalog includes all of the second-hand equipment which the company now has ready for immediate delivery.

Wooden Pipe. Redwood Manufacturers Co., San Francisco. Catalog VIII; pp. 109; illustrated.

A general detailed description is first given on the method of manufacture of the pipe, its uses, strength, etc. Drawings showing the way in which the pipe is constructed and put together on the ground are reproduced. A table and reproduction of letters from users of the pipe are given, with tables of use in constructing lines and also some of general use in hydraulic work. Costs, prices, etc., are also given as also are layout drawings of various installations.

Air-Compressor Condensing Intercooler. MacCamy Air Cooler & Condenser Co., Salt Lake City. Pamphlet; pp. 8; illustrated.

Letters from users of this type of intercooler are reproduced and the advantages of the equipment are spoken of. Water in the compressed air is a well known source of considerable trouble especially when used to operate rock drills. The intercooler as described in the text of this pamphlet can be installed with any kind of air compressor and will tend towards eliminating the greater portion of the water in the air while passing from the low to the high compression cylinder.

INDUSTRIAL AND TRADE NOTES.

The Carbo Corporation has removed to Chicago Heights, Ill.

O. E. Thaleg, who has been connected for some time past with the Austin Mfg. Co., was recently appointed district manager of the power and mining department of the Worthington Pump & Machinery Corporation, with offices at 825 Old Colony building, Chicago.

Executive control of the Moore Filter Co. has again passed into the hands of Henry B. Haigh and several associates, who have plans for carrying on the business on a much broader scope, the details of which they are not prepared to give at this time. Mr. Haigh assumes the office of president of the company, which position he held for a long while with the old company, and under his experienced handling the business should progress to the best interest of all concerned. Their new offices will be located at 43 Exchange Place, New York.

Late News From the World's Mining Camps

Editorial and Special Correspondence.

ALASKA.

The ore deposits of the Prince William sound region may be grouped broadly into two classes—copper deposits and gold-bearing quartz lodes. The mineral associations in both gold and copper deposits are in general the same, so that the copper mines produce large amounts of gold or silver or both, and copper sulphide is present in small amounts in many of the gold quartz veins. The known productive mines on Prince William sound in 1915 include four copper mines and five gold mines. A much larger quantity of copper ore than of gold quartz was mined and treated, and the total value of the metals produced from the copper ores was about five times that obtained from the gold quartz ores. The value of the total mineral production of the Prince William sound region in 1915 was \$1,340,000 as compared with \$1,200,000 in 1914. The above information, as well as a detailed description of the mines and prospects visited, is contained in a report entitled "Mining on Prince William Sound, Alaska," by B. L. Johnson, recently issued by the Survey as Bulletin 642-D.

Kennicott.

With D. K. McDonald, president, and M. E. Hay, vice president, Spokane, Wash., a company was recently formed to take over the Josevig-Kennicott claims. It is building a road from the Bonanza mine to the property. The road extends 6 miles across the Kennicott glacier, and three miles on the mountain-side from the end of the glacier to the workings. The company is now shipping in supplies and a large crew will be put to work next spring.

It has already shipped 3 tons from open cuts on the vein which it is estimated will run from 40 to 45% copper. Mining engineers estimate that there are 600 tons of 40 to 50% copper on the surface.

Valdez.

Developments are showing good results on the 210 and hoist levels at the mines of the Granite Co. This is made authentic by recent reports of President B. F. Millard, who further states that assays show on the hoist-level 10 ins. of \$71.10 ore, 8 ins. of \$295.58, and 14 ins. of \$166.19. This also holds on the 210 level. We are getting high-grade there, and have had a continuous shoot for 250 ft. On the 350 level we are getting \$1 ore. Starting at 50 cts., it is getting better all the time as we go in, and I believe when we get over to catch the shoot of rich ore on the 210 level we will have it as good on the 350. The average of the 210 level for month of August was \$16, and the vein averages 38 ins. wide. The hoist level on the granite side is showing up rich. We followed the fault on the slate end of the 350 level 80 ft. to the right and picked up the vein with milling values. This gives us ore on three levels and no doubt it continues from one level to another. I still hold that our best ore will be found going into granite and perhaps on the upper side of the dike. We have had trouble getting good miners and had to fill up with black men. Developments at the Black Diamond group are encouraging and plans are being made to operate through the winter. The Black Diamond covers two veins. One is the same that runs through the Three-in-One. The other is a parallel vein several hundred feet away. Both of the veins have been traced the full length of the claims. Considerable development work has been done. This work has demonstrated that the ore in the lead crossing the Three-in-One carries the same values on the Black Diamond as in the former property. On the parallel vein, where work is at present being done, it has been demonstrated that this vein carries ore equally as rich as the other. Frank Kampfer, in

charge of operations, expects sufficient ground will be blocked out by spring to warrant a mill.

Unga.

With eight men, Engineer A. H. Bradford is opening up two quartz veins near here. Outside capital is backing the enterprise and are Messrs. Deming, Smydecker and Scottem, big owners in the National mine, Nevada. There are two ledges that can be traced for over 2 miles. One lead is 200 to 250 ft. wide and the other 100 ft. In one ledge assays have shown \$2 to \$14. The other assays from \$1 to \$4 have been returned.

Nome.

An area which created excitement 6 years ago has again come to light. A strike has been made in the district around Fort Davis on the second bench-line. Jensen located the pay at a depth of 20 ft. Development so far accomplished is slight but is said to be sufficient to show that the strike is of more than passing value. The streak is 2 ft. thick. According to statements it pans as high as \$7.

Development at the property of the Pioneer Mining Co. is progressing and gives promise of blocking out sufficient ore to keep up production next season. During this season about 15 tons of high-grade was produced.

ARIZONA.

Ray.

Ray Hercules Co., it is said, has purchased nearly \$1,000,000 worth of materials and machinery. One order being for a head frame, structural steel and corrugated iron, which was awarded the El Paso Bridge & Iron Co.

This will provide materials for all the buildings required at the property. An order was placed with McIntosh & Seymour for a Diesel engine.

On account of the congested conditions the contracts provide for delivery in from 5 months to a year, and include material for a mill, hoist, compressors, crushers, ore bins and such buildings as are necessary for the offices and the accommodation of the employees. Callow flotation machines will be used in a system similar to that of the Inspiration and Magma companies. Two shafts have been sunk. The main one is 750 ft. deep. About 150 men are employed. Bodies, running from 6 to 10%, have been encountered. Regular shipments of carbonate are being made to the El Paso smelter. In the main shaft native copper was encountered between the 600 and 700 levels. Three shifts are working continuously. Churn drills are being employed in prospecting, some having penetrated to a depth of 600 to 1500 ft.

Globe.

A complete system of development is to be started at the Iron Cap Copper Co.'s property through the Iron Cap and Williams shafts. The equipment at these shafts will allow a depth of 1500 ft.

The old Iron Cap shaft, 400 ft. deep, has been enlarged to 3-compartment shaft and sunk to the 800 level. A cross-cut was started at 600 ft. As soon as the station at 800 is finished crosscutting will begin at that level. The shaft is to go down to the 1000 or 1200 level and the area north of the shaft explored. The shaft is situated 1000 ft. from the east workings of the Arizona Commercial on the Copper Hill lode, which is 30 ft. wide and averages 6% copper. Indications are that the lode crosses Iron Cap ground 300 ft. north of the shaft and extends $\frac{3}{4}$ of a mile through the property. The crosscuts at the 600 and 800 levels should reach the sulphide vein in a few months. At the Williams shaft a

double drum hoist is being installed. They will sink from the 900 to 1000 level. The vein on the 800 proved large and rich in both copper and silver. Almost continuous shipments of ore have been made from that level for 3 years. In the winze sunk 90 ft. from the 900 level rich ore was found. It is 7 ft. wide. Three feet is bornite, which assays over 30%. The equipment at both shafts is adequate for development to the 1500.

Oatman.

The great lode system which traverses the central portion of the district, and upon which are located the Tom Reed United Eastern and Big Jim mines is an immense lode. Recent developments on the easterly extension of the Tom Reed which covers fully 1½ miles both to the east and west of its main, or Ben Harrison workings, have given further and most interesting proof of the importance of this great lode system.

From the extreme western point in which the United Eastern has developed great bodies of pay ore, to the extreme eastern point at which the Tom Reed has developed large bodies of pay ore, is almost 2 miles. Here seems to be a practically continuous ore body, held in two enormous veins on either side of a strong dike system. These veins average more than 15 ft. in width, and have been developed at various points to depths ranging from 200 to 1400 ft., and show pay ore to the greatest depth, and up to within 50 ft. of the surface. In addition, along this great zone, about 1 mile to the west of the United Eastern, the Tom Reed is opening pay ore at 100-ft. depth in its Rhine gold claim. When it is considered that this ore body is free milling, showing no sulphides, from top to bottom, that it is more than 15 ft. in width, and that average values seem to be well above \$12, the characterization of the lode as "amazing" seems to be justified. During the past 2 or 3 years, the ore extracted from the Tom Reed's main workings has given values of more than \$20, figuring averages year by year. There seems reason to believe that the above estimate of \$12 per ton is far too low.

The longest ore shoot in the main workings of the Tom Reed mine is less than 300 ft. There are three practically parallel shoots in these workings, which have enabled the payment of some \$2,555,000 in dividends to date, and this when mining and milling costs have been very high. The new easterly workings of the Tom Reed, in the Black Eagle, Aztec Center and Bald Eagle workings have opened a continuous ore shoot at 400 ft. depth which is known to be more than 800 ft. in length, and which gives promise of being 1100 ft. in length. Conditions indicate that foot for foot, these new workings rival and will continue to rival, under development, any like footage in the old workings. In other words, Tom Reed seems to be entering upon a new era of life. It also seems tenable to believe that the new workings will result in a much larger mine than the old mine of the company. Supt. Edwin Rabb, who made such a success of the Tennessee mine in Chloride, and who was field man for Phelps-Dodge in Mexico before the revolution, states that he believes these big bodies of free-milling gold ore in this district should be mined and milled at a cost of much less than \$4, and he is making plans in this direction. He has already materially reduced the costs of mining and milling Tom Reed ores.

The United Eastern has its new 200-ton mill more than 80% complete. Housing is about completed, and all machinery is on the ground and is being installed. The new main working shaft is now being connected with the lower level of the old workings, at 665 ft. depth, or 750 ft. depth in the new shaft. It is anticipated that the mill will start operations in December. Ore reserves are estimated at more than \$12,000,000, and that average values are well in excess of \$15.

The Big Jim, the property of which cuts into the central section of the Tom Reed ground immediately to the west of its main workings, is also developing into a splendid mine. Ore has been developed from a depth of about 60 ft. below surface to 485 ft., and for a lateral length of more than 650 ft., proving a continuous ore shoot. The vein averages more than 20 ft. in width, and all its content will be sent to mill. Careful mine sampling seems to indicate that average mill

returns will be in excess of \$12 and possibly close to \$20. Careful inspection, measurements and sampling indicate that there is now in this property an actual ore exposure of 290,000 tons, and that work in progress should within the next 60 days expose another block 200 ft. in length, 345 ft. in height and 20 ft. in thickness, or 115,000 tons additional.

In the Black Range section of the district the Nellie, at a depth of 350 ft., has encountered its main vein, and sampling showed 17 ft. of ore, with the foot wall not yet in sight. The vein filling is calc-spar, blackened by manganese oxides, and replaced with adularia quartz to fully 50% of its entire bulk. This is the condition which, in this district, is necessary before deposition of metals is expected. The entire crosscut panned well, and the first 9 ft. showed average values of better than \$12. The remainder has not been sampled at this time. When the vein is completely crosscut, work of drifting to the east, under a rich ore shoot which shows at surface, will be started.

The Ivanhoe is now pumping out its workings, having installed a powerful compressor plant, and work on the 500 level will soon be resumed. When the miners were flooded out, a full face of adularia quartz was showing which was really commercial ore. This seems to be at a point where the feeder vein which the drift has been following, joined the main vein. The water which came in prevented the discovery from being followed up to prove its importance. Engineer Keating, who has made such a success of the Big Jim, is now also in charge of the Ivanhoe, and expresses his opinion that it will make into a mine.

The Adams, in this same section, will soon begin lateral work, and as its surface showing is spectacular, interesting developments are expected when its vein is crosscut at 400 ft. depth.

The Black Range is working on an old shaft, 150 ft. deep, near the Nellie Endline, and on the same vein, about 800 ft. to the east of the Nellie shaft. Some ore better than \$20 is being encountered.

Chloride.

The management of the Georgia Mining Co. received orders to put on three shifts and sink to the 300 immediately; may have to install compressor and air drills account bad ground.

Black Jack has exhausted ore sack supply, compelling suspension ore shipments; breaking of ore in mine continues; high grade copper ore is found in upper tunnel.

Silver Hill announces mill construction to be commenced immediately. Fifteen thousand tons of ore are on its dumps and big reserve in old workings; may add custom department.

Representatives of Grasselli Chemical Co. of Cleveland are here looking over the field for ores, and with a view to installing sampler for the company.

The head of Western Ore Purchasing Co. is on the way here to survey the field for another sampler.

F. M. Steffy is coming to start work on new 250-ton custom mill.

Robert Mead Martin, of Los Angeles, is in camp superintending construction 150-ton reduction plant on Copper Age property.

Schenectady, contiguous to the famous Tennessee, opened 2 ft. shipping ore on 175 level.

The Emerson started up with five men; old workings are being cleaned out; good values are being found, as represented by old timers.

Santa Fe railroad will put motor service on to Kingman to accommodate inrush of people.

Power line is within half a mile of town. Plans of the company have been enlarged three times since construction began, due to unprecedented growth of town and mines.

Tennessee mine is adding counter-weight to shaft equipment to make ready for new double-deck cage. The force of miners will be increased as soon as raise from 1400 level reaches surface.

Rich ore has been found by Frank Braly more than mile from camp, on flat. Enlarges known mineral zone in that direction.

CALIFORNIA.

Jackson.

The strike situation is gradually improving, and hopes are entertained for capacity operations at most mines before the end of November. Work has been resumed at the Bunker Hill with 60 men, and the management expects to have fully 100 on the payroll soon. At the Kennedy 120 men are employed, and the Argonaut has over 100. The Plymouth Con. is working a large force and maintaining a heavy output. The South Eureka Co. has established a guarded camp at its property, and is quietly arranging to resume work at an early date.

Since the strike began fully 500 miners have left the district, including a large number of the most hostile agitators. Attempts to settle the trouble by arbitration have been defeated by the companies, which contend that there is nothing to arbitrate. To grant the wage increase asked would mean the forced idleness of many properties, and no other provision than the demanded scale would be accepted by the miners.

Several old properties in this district are being examined with a view to resumption of activities. Among these are the Mammoth, Mitchell and St. Julian. It is reported a sale is being negotiated for the St. Julian, the prospective buyers being James S. Rear and T. M. Woode of Vancouver, B. C., owners of the Columbia mine and other important California properties.

The elevated tramway from the ore bins of the Argonaut shaft to the new mill is nearing completion. It will be approximately 800 ft. long and provided with double tracks, the descending car aiding to balance the one ascending. Construction of the mill has been practically completed. In addition to the equipment of the old 40-stamp plant, the new mill will be provided with 20 heavy stamps and special gold-saving devices.

Sutter Creek.

Unwatering of the Old Eureka mine is proceeding rapidly. A powerful double-drum hoist, capable of raising a 15,000-lb. load from a depth of 3000 ft. is being installed and a centrifugal pump has been placed in position to elevate water to surface from the 9000-gal. tank on the 500 level. Unwatering of the 800 level is proceeding steadily. The miners are beginning to find numerous charred timbers, mute evidence of the fire that forced the closing of the mine more than 30 years ago.

Kennett.

Construction of the electrolytic zinc plant is proceeding rapidly, and the management expects to start ore treatment within a few weeks. Frame work is in position and considerable machinery has been installed. The plan represents an expenditure of \$300,000 and will treat custom ore in addition to treating flue dust from the baghouse of the Mammoth smelter, and zinc ores from the Mammoth mine. It will also probably handle a heavy tonnage for the Bully Hill smelting people.

In the Arps group a 6-ft. vein of gold-silver ore assaying around \$70 has been intersected. The vein also carries some copper and is developing well. The owners of the Shasta Belmont are arranging for early operations. The lower tunnel will be extended 160 ft. to intersect the main ore zone, and an engine and blower installed. The camp will also be enlarged and the road repaired preliminary to shipping to custom smelters. In the upper tunnel some good ore has been blocked out. The zinc ores will probably be treated in the new Mammoth plant. W. E. Casson, of Carson City, is manager.

Sonora.

The Confidence mine has been acquired by the Confidence Gold Mines Corporation, capitalized at \$600,000. There are 1000 preferred shares, and 5000 common. The directorate is composed of Warren B. Hunting of New York, and E. S. Bolen and W. A. Stratta of Richmond, Va. Comprehensive operations are to be commenced immediately. The Confidence was long one of the most consistent producers of the Sonora district and has produced upward of \$5,000,000 in gold but idle 10

years. It contains wide bodies of medium-grade quartz in the lower workings and has been opened to a depth of 1100 ft.

Rich ore has been opened in the Gem mine, for the past 4 years worked by J. F. Wulzen. The ledge ranges from 3 to 4 ft. wide and was struck in a winze recently started from the end of an old adit. Considerable free gold shows and the strike is considered one of the most important made on the East Belt in years.

Morris Ravine.

Machinery is being installed at the Bumble Bee quartz property, controlled by Ford brothers. Large quantities of electrical equipment is being installed at the Banner mine, and the management expects to start large-scale operations early in December. Good ore is showing on several levels, particularly in the main workings of the South Banner claim.

Angels Camp.

The Estelle Gold Mining Co. has been formed by Denver capitalists to operate a group of claims in this district. The property lies near the Gold Cliff, Angels, Utica and other large producers, and comprises a merger of numerous holdings of great promise. Machinery has been purchased and it is planned to start active operations within 30 days. Ralph M. Jones is president; Felix B. Tait, vice-president; Estelle Sibbald, secretary-treasurer; Daniel F. Mackay, general manager. All are residents of Denver.

Downieville.

The buildings and headframe of the Finney mine have been enclosed and roofed in preparation for the winter. A new hoist is in position and sinking on a goodlooking ledge is making fair progress. It is intended to continue work all winter and to provide reduction facilities in the spring if ore conditions remain satisfactory. George Morse is superintendent.

It is reported the Rock creek section will be supplied with electric power in the early summer. A preliminary survey for the transmission line has been made from the North Fork mine to the Wisconsin, and it is said branches will be extended to all the principal mines.

Tuolumne.

Unwatering of the Columbus mine has been completed and mining will be resumed with the least possible delay. It is one of the oldest properties in California and in its early years yielded much rich ore. Strongly-financed eastern people recently became interested, and a vigorous campaign of development work has been outlined. The Buckeye mine has passed into the hands of New York people and is to be re-opened within 30 days.

Nipton.

The Copper King group of nine claims, belonging to G. H. Hamstadt of Nipton, has been bonded by W. W. Wishon and H. B. Sharps, representing Philadelphia interests, and their examination in the next 60 days will determine the sale. They have four assistants in making the examination now on the property.

COLORADO.

Silverton.

The Pride of the West Mine has been leased by C. W. Byrd and associates. Production will be kept up during the winter. The ore is now being shipped to the Silver Lake customs mill, but will later be treated at the Old Green Mountain mill, which is now being remodeled, including the addition of flotation machines.

Cripple Creek.

The Albert-Beacon Gold Mining Co. is operating the Beacon mine under lease with the privilege to purchase. An electric hoist has been installed at the old Beacon shaft. Just as soon as the old sump is cleaned out, men will go to work in the old levels. Other miners will start sinking the Beacon shaft from its present depth of 360 ft. an additional 300 ft. Two shifts will probably be put to work.

Associated with J. D. Purcell, president of the Dearborn Chem. Co., Chicago, Matt. Korf has taken a lease on the Victor mine from the Smith-Moffat Mines Co. Under the

lease conditions Korf is given permission to operate the Victor through the Lee shaft of the Isabella Co., on whose ground he is now leasing, and with this favorable concession from both companies, the drift on the Cheyenne, at the 500 level of the Lee shaft, will be extended through into the Victor ground.

Georgetown.

In the 5th and 6th levels of the Mid-Colorado mines good ore is being worked. In the Moline tunnel level at a depth of about 1000 ft. a 6-ft. vein of lead-zinc has been opened. It is being contemplated that the company's mill will be re-modeled. The plans include a Symons disc grinder to replace the rolls, also a double deck Deister table and flotation unit. It will be necessary to provide either aerial tram or otherwise transportation for ore now being mined in the Moline tunnel to the mill. The present tramway has its terminal above this level.

Crosscutting is in progress at the Onondaga mines to get the footwall of the vein from the 180 level. Three separate veins have been encountered in this work. Two of the veins are solid enough to pay, the ore being mostly galena. There is a good body of ore in No. 3 raise, which is now up to the 180 level, but quite a distance south of the main workings, thus making four veins running through the lode. When the footwall is reached by the crosscut it is expected that a large body will be opened. At present no ore is being mined, and there will be none until development now under way is completed.

Silver Plume.

The Smuggler mine, which is now operated by the Holling-worth Mining Co., is producing 500 tons of lead-zinc-silver ore per month, as against 100 tons at the first of the year. The shaft is down 400 ft. with 5 levels. The 5th level is out 600 ft. from the shaft, and a stope 300 ft. long is being operated, though the last 100 ft. has only just been timbered. The ore averages 20 ins. wide. There is stoping ground to surface at the further end of the level. In the bottom of the 5th there is a 20-in. body showing for 100 ft.

Leadville.

At the Bartlett mine, operated by the Prince of Wales Leasing Co. water has been encountered in quantities causing much difficulty. At present, work is being carried on from the bottom of the interior shaft. Drifting from the winze has gone out 50 ft. One big shoot of silver was mined through the Bartlett several years ago and it is the continuation of this vein that present operators are striving to reach. It is believed that the flow will rapidly decrease as soon as cold weather prevails, making it possible to continue work without the necessity of enlarging the pumping capacity. Enlarging the pumping plant, however, is contemplated for the spring if the vein is encountered in the meantime.

The vein opened in the ground of the Fidelity Gold Mining Co. is now proving to be persistent and is acting as an incentive for the beginning of operations of many other properties in the district during the coming season. The company expects to add considerable to both its plant and number of employees.

Idaho Springs.

Good ore is showing in three places on the 130 level in the property of the Consolidated Mines & Dev. Co. One drift showing 6 ins. of smelting ore, assaying \$60 and 1½ ft. of mill dirt, which assays \$10 gold and 5 ozs. silver. The raise being driven in three compartments and a timber slide to afford a method of getting timbers into the mine, has cut into the surface shoot of ore and has a 2-ft. streak from which \$16 to \$30 gold and about 8 ozs. silver are returned. The other heading on the level has 5 ft. of \$10 mill dirt, with a small streak of smelting ore on the hanging. The company has completed a new building at the portal of the lower tunnel, consisting of change room and shop, and will start this level with two shifts Nov. 1. The level will be driven under the Silver Moon vein, which is now worked on the upper level, cutting the vein at a depth of 3000 ft., and on through to the Gold Quartz vein, a distance of 500 ft. from the present heading, which is 575 ft. in. Preparations are being made for the installation of a compressor and machine drills. Later it expects to erect a mill at the portal of this level.

GEORGIA.

Dahlonega.

The Barlow and Briar Patch placer mines are being operated by leasers. The power plant at the Pyrite mine is being installed by John Sargent.

Tonson and Cowan are carrying on a series of mill-run tests, handling the ore from the Smith shaft, and also the saprolite ore from the tunnel. Cyanide tests are being made on all the ores with satisfactory results. The shaft being sunk on the Johnson vein has opened a good body of ore, at a depth of 24 ft.

The Crown Mountain mill is running 20 stamps on ore from the Wallace sand vein and hope soon to be running 50. The Crown Mountain Mining & Power Co. is working a regular force of 12 in the upper Wallace shaft and tunnel, sinking the incline shaft and driving the tunnel west. Both headings are in ore of good grade, and it is being sent to the mill. It also has some men opening the lower Wallace and soon expects to have that vein sending ore to the mill. It is making some mill-run tests of 20 tons each from the sand vein in the Columbia cut. A. H. Head has charge of them and is making tests of all ores milled and mined, to determine the actual percentage of recovery by amalgamation, in order that subsequent treatment of the tailings by cyanide or flotation can be installed when necessary.

IDAHO.

Wallace.

The ore reserves in the ground above the No. 4 level of the Interstate-Callahan mine, the third largest zinc producing property now operating in the world, have been materially increased by development the last few months, according to D. F. Haley, consulting engineer for the company, and that the mine never was in better physical condition, and the outlook for further profitable development is decidedly promising. Drifts have been extended 300 ft. on both levels above the No. 4, the main hauling level, and are still in ore. The addition of 300 ft. exposes the body for 1000 ft. in all, whereas we had calculated on but 700 ft. Conditions suggest that the body may prove to be as long as on the lower levels, where it has been followed for 1300 ft. It is 7 to 15 ft. wide, and 18 ft. wide in places on the upper levels. Ore struck recently on the 700 level, where the depth is 1600 ft. has been drifted on for 400 ft. It is 7 to 30 ft. wide and its average quality is as good as the rest of the mine. The mill feed has been running 28% zinc and 6% lead the last 18 months. On the 500 level, which is 425 ft. above No. 7, we have installed 43 chutes and have ore in the face of the drift. This provides a continuous stope 1300 ft. long in the richest ore we have had. Plans and the organization have been completed for the flotation plant, the construction of which will occupy but 2 to 3 months. Impounded tailings will be removed from the dump to the plant by an automatic drag. The expense of handling by this method is but 8 to 10 cts. a ton in other places. The tailings will be ground in a tube mill and passed on to the flotation section. We have 250,000 tons that range in content from 1 to 7% and figure that an even 1% can be handled with profit. When the flotation plant is in operation we expect to recover 93 to 95% of the zinc values and to increase the saving on lead considerably. Operations have been started on the Nipsic mine, where we expect some developments of importance."

Wardner.

The Stewart Mining Co. is negotiating for properties adjoining the Stewart, and also is seeking the right, under lease to develop and extract ore beneath the streets and alleys of Wardner, and under private property in the mining town. The lease is to run for 25 years, under payment of 5% royalty gross. Mayor B. Flaig and the board of aldermen have signed the lease for the city, and practically all the owners of private property have signed. The leases

are made in the name of William A. Beaudry, managing director of the Stewart Co., and his activities in this regard have caused considerable speculation. It is understood that Beaudry has first chance at the Slavonian property, adjoining the Federal and Bunker Hill holdings at the upper end of Wardner. Rumors are also current that he is negotiating with the North Bunker Hill Co. for a control of that property, which covers a part of the Wardner townsite. It is reported that a shaft is to be sunk 1000 ft. below the Main street level, and that an effort will be made from that depth to reach the main leads crossing between the Bunker Hill and Stewart veins to the south of the Osburn fault.

Kellogg.

In a report to stockholders, covering the last year's operations at the property, President W. W. Papesch, of the Highland-Surprise Mining Co., states that conditions now are better than at any previous period of the corporation's existence. He says: "Important new ore bodies have been opened by development during the period, and a successful treatment method has been devised for the mill, enabling us to make a much better metal recovery than formerly. The changes in the plant were made on the recommendation of the mill superintendent of the Federal Mining & Smelting Co., who is a recognized authority on concentration and flotation of lead-zinc ores. We now are producing 20 to 22 tons daily of high-grade concentrates, and we intend to install additional equipment to increase the output. The outlook for having the property on a paying basis soon is exceptionally good. The O. W. R. & N. now has two crews of surveyors establishing a route for a branch line up Pine creek, and there is a settled belief among men in touch with the situation that the road will be built early next year. This will bring transportation right to our property, enabling us to increase our production and reduce operating costs. It also will prove a boon to other companies operating in the districts, including the Constitution, Douglas, Nabob and several others that are developing their holdings."

LAKE SUPERIOR.

COPPER.

Houghton.

Allouez's management has filled the vacancy caused by the resignation of its head captain by the appointment of Albert Watters, who has been shift boss there for some time and who has had ample experience there and at the Champion.

Mayflower and Old Colony have agreed on a consolidation by which one share of new company to be organized will be issued for a share of each of these companies. An assessment of 50 cts. a share will be called on the stock of the Old Colony so as to bring its treasury funds up to those of the Mayflower, making about \$100,000 as the working funds of the new company. The first work will be the sinking of a shaft.

Michigan is now in the lode supposed to be the Evergreen, with the main crosscut having a width of about 36 ft.; the 12 last ft. have laid bare considerable heavy copper with a little of stamp grades—almost enough to be of commercial values. After the crosscut has been driven far enough so that the work will not interfere, some drifting will be undertaken as commercial ground according to the character of these lodes should soon be met with. The work on the hanging wall of the Ogimah amygdaloid is somewhat poorer ground; that at the western drift of the Butler lode is still in broken ground and is yielding but little copper, which is of stamp grade; the eastern is still pushing on up towards the 5th level encountering some of the stamp grades.

Isle Royale has a daily output of 3000 tons and had the highest tonnage in its history in October. In August and September, because of the scarcity of men, it fell off somewhat; but for the 10 months previous it had been gaining each month. This increase is only the beginning, as the northern end has not been mined to any depth, and that at only one shaft, No. 2, and only to the depth of the 30th

level—No. 1 being down about 1600 ft., No. 4 to the 17th level, No. 5 and 6 still shallower, and No. 7 only to the 7th. There will be one and probably two more shafts sunk to the south.

Cherokee has, counting the width of the shaft, over 35 ft. of the best ground yet disclosed in the crosscut driven to find out the width of the vein. The copper is of the same heavy grade and comprises much small mass and barrel as encountered in the blast made across the lode at the top of the ledge. President W. A. Hodgson, who is managing the property for the directors, says that as soon as the width is ascertained sinking will be resumed.

New Baltic has carried its shaft pit down to 40 ft., and although it has its timber already, it has not found it necessary so far to put them in, and probably will not have to as boulders are now being met with—an indication of the nearness of the ledge which should be met with according to the diamond drill cores within 50 ft. of the surface. In a few days the ledge should be uncovered, and then the timbering will be set up and drilling begun.

The Powell-Anderson-Jones lands north of the eastern end of the White Pine are being explored by the E. J. Longyear Co. after a thorough examination by their own geologist. Two drills are in operation and the work will be pushed. By many who have inspected these lands, the possibility of their carrying paying grades is considered most promising, as it is thought that the White Pine beds or those similar will be encountered, the formations seeming to favor deposition.

New Arcadian on the southern drift of the No. 2 shaft which is located on the old Arcadian lode, is finding values fully equal to those found by the crosscut from No. 1, though the northern is in somewhat poorer ground. The work of sinking is somewhat slow at No. 1 shaft, as the old engine cannot be used below the 1250 level and since the work of finishing the rockhouse has been interrupted. But in 3 or 4 weeks everything will be ready so that the new hoist can be used to the bottom, when much more development can be done, as it has been difficult to hoist while the construction of the rockhouse was in progress.

Hancock will have an output of over 25,000 tons for October, with a prospect of a further increase for November; the figure for September was nearly 23,000. A few men are being taken on and the stoping correspondingly increased.

Franklin has been for the past 15 days forwarding over 1300 tons daily to its mill. Its mechanical haulage system, comprising a compressed air engine with ropes, on the 29th level, is in successful operation in a rich stretch of ground, so that the yield as well as the tonnage will be benefited from the improved method of haulage.

Algomah has had its boiler on the ground for about 2 weeks, and as the same building will be ample for it, and as the foundations are being laid, it will not be long before the sinking of the shaft from about the depth of between 400-500 ft. will be resumed.

Houghton Copper is getting from the Superior lode on the 4th level and the 6th, about two loads of rock daily, which aid considerably in caring for the exploration expense. This rock is said to run at the Winona mill between 15 and 17 lbs. a ton.

IRON.

Ironwood.

It is now anticipated that the Munro mine will commence sending ore to the Escanaba docks by Nov. 15. This depends upon the speed attained in erecting the new shaft-house and in repairing the machinery.

Republic.

The Kolman mine has been leased to Mr. Hymens, who is now dewatering the underground workings. His exploration work will be centered mostly on exploring for deposits at some depth since surface deposits were drilled for some year ago without success by the Cleveland-Cliffs Co.

Since the Republic mine has been operated by the Cleveland-Cliffs Co. the two shafts which are now operating the No. 9 and Pascoe, have been pushed down to the 2220 and

2120 levels respectively. The mine has shipped to date about 220,000 tons and will keep its steam shovels active until the close of navigation, sending down better than 225,000 tons before the close of the season.

Ishpeming.

The Hoose & Person Construction Co. have contracted with the Cleveland-Cliffs Co. for the stripping of a large territory at the east end of the old Lake Angeline mine. Cleveland-Cliffs is building a new flume that is to take the water of the east end of the old lake basin out by way of the Salisbury mine, and leading it away from its former course which finally led to the Holmes mine locality.

Ashland, Wis.

A law, it is expected, will be placed before the Wisconsin legislature at the next session making a state tax of 10 cts. per ton on iron ore mined in Wisconsin and an additional tax of 2 cts. per ton on iron ore shipped through the docks at Superior and Ashland, the 2 cts. per ton to go to the cities. In informal talks it was pointed out that the ore is mined in the state at little expense; shipped east and there handled in manufacture at a further expense of about \$10 a ton; comes back in the form of a finished product from which the manufacture derives as high as \$350 per ton; that under present conditions the exploitation of the iron resources is similar to the conditions under which the pineries were denuded a few years ago.

MISSOURI-KANSAS.

Joplin.

October has been one of the strongest in market conditions since early summer. November opens with an equally strong position for all classes of ores produced in the Joplin field. With a rush, zinc prices went up to \$85 for the week, which is on a par with lead ore prices during the past few weeks. With such strong prices prevailing there has been a steady decline in the stocks of ore, and strenuous efforts on the part of mine operators to bring their production up to the maximum while prices are so good. The only feature inimical to the district's welfare is the power situation and the failure of rain sufficient to supply surface water for milling. The continued drought into the fall months is becoming more and more of a problem, and about all the expedience for temporary relief has been exhausted. This week sees a number of new mines forced into idleness on this account, and the continual lowering of water in the rivers is decreasing the power output of the electric power company to such an extent as to lower the number of mines operated.

This week came the announcement of the entrance of Chas. T. Orr's mining companies into the smelting field. Arrangements were completed for the building of a 5-block smelter at South Ft. Smith, Ark., where the city has donated a smelting site, and a very cheap contract for natural gas was secured. Approximately \$200,000 will be expended in the erection of the plant, the contract being let to the United Iron Works of Joplin.

Orr controls a very large output of zinc concentrates in the Duenweg and Webb City camps, he being the manager and one of the principal owners in the properties of the Athletic Mining Co. with two plants, and the Bertha A. Wingfield mines north of Webb City. He also owns personally the Big Six fee and lease, upon which there has been considerable production during the past year. The new plant will doubtless handle all of these properties, together with ore purchased in the Joplin field.

A prospecting company made up of W. H. Walker, Joe Walker, K. H. Warren, J. C. Warren, and J. F. Brewer, all of Joplin, have secured a lease southeast of Joplin, and are drilling it. Three holes have been put down, two of which showed good ore below the 100 level. The drilling will be continued until the entire lease is prospected.

On the Taylor land northwest of Joplin the Big Run Mining Co. has opened up a very rich deposit of ore at the 140 level where a 14-ft. face is being worked.

On a 42-acre lease of the Playter-Glover land west of

Joplin, the Sparkler Mining Co. has driven two prospect drifts into some excellent disseminated ore which is considered the best yet opened up by the company. Owing to the difficult power conditions now prevailing, the company has to operate its mine during the day and mill its ores at night. This company has one of the largest plants in the Chitwood camp. Those interested in the company are O. W. Sparks of Galena, Kan., E. Wilkerson of Joplin, W. F. Scott, R. O. Larson of Kansas City. The Lead & Jack Mining Co. has undertaken to drain the old Porter land on East 7th St. and has installed a 12-in. centrifugal pump which is gradually lowering the water. Efforts are being made to drain the tract to at least the 100 level, and efforts are being made by sub-lessees to work a deposit known to exist at the 80 level. Present operations are being conducted at the 33d level, and with the gradual lowering of the water it is expected that many sub-lessees will resume operations on this old tract.

Spencer & Co. are starting the erection of a new sludge mill at the No. 3 A. W. C. Mine west of Joplin. The company contemplates the installation of at least eight sludge tables and it will be so built that the capacity may be doubled. Those interested in the company are J. S. Spencer and W. W. Holmes of Webb and Don Molloy of Joplin.

Aurora, Mo.

The Aurora Con. Mining Co. is erecting a new 200-ton plant on its lease at Aurora. The framework of the mill is up and the installation of the machinery is well under way. The company is installing electric power and expects to be able to start its plant within the next 30 days.

The Daisy Bell Mining Co. is electrifying its plant which is producing about a carload of silicate ore each week.

The Old Baldwin mine sub-leased from the Old Contract, has opened up a fair deposit of ore which was sufficient to encourage the operators to erect a concentrating plant, and plans are now under way for this work.

Galena, Kans.

Work has been started on the erection of a plant at the Double Lew Mining Co., which has developed a mine on a 12-acre lease of the Paige land just south of Weyland mine. The company expects to get its plant in operation within the next 60 days.

On the B. M. Robinson tract of ground northwest of Cave Springs, extensive prospecting work is now under way by the Century Zinc Co., which is testing out a 10-acre tract and reports from the drilling indicate the 35-ft. face of ore at the 125 level. B. M. Robinson is also sinking a shaft on the same tract and is now taking out ore at the 130 level, but is sinking the shaft down to the 200 level; and prospecting has shown the existence of a very rich deposit of ore.

MONTANA.

Butte.

Bidding \$673,717.42, the minimum price stipulated by the court in the dissolution proceedings in which the directors of the Atlantic Mines Co. asked permission to dispose of assets and dissolve, the Anaconda Mining Co. has become the owner of the Lexington and a score of other claims in the Walker-ville district. The Lexington and some of the other claims sold at one time belonged to the La France Copper Co., a Heinze holding. Three years ago they were taken over by the Atlantic Mines Co. and the present proceeding is a formal step in the disposition of the assets of the dissolving company. The property has for some time been in the hands of the Anaconda under what virtually amounted to a purchase, which now is confirmed by the legal sale. It is expected that the perfecting of title to the property by the Anaconda will open up the road for a more aggressive development of the properties and with the present high price of silver, the consummation of the sale presages stimulated activity in the Walker-ville district.

From a bid-price in the neighborhood of \$3.50 per share, the shares of Butte & Zenith City have doubled in the past 6 weeks and sales at above \$7 were reported last week. Supt.

William Gibson, who has just returned to Butte from a business visit east, states that development of the property is progressing in a manner most gratifying to the management. Two of 10 known veins have been cut within the past few days and no drifting as yet has been done, the two fissures of well mineralized ore being intercepted in the cross cutting. These veins were cut on the 1000 level and are found to carry copper values of from ½ to 1% copper, with in excess of 2 ozs. of gold and slight traces of gold.

Anaconda's output of copper for October was 31,500,000 lbs., an increase of 2,100,000 over the September record. This mark is within 1,800,000 of the total established in April of this year when the greatest amount of copper in the history of the company was produced. October figures bring the total for the year to 265,400,000 lbs. The production by months was as follows: January, 23,200,000 lbs.; February, 23,300,000; March, 26,500,000; April, 33,300,000; May, 30,000,000; June, 28,100,000; July, 28,200,000; August, 28,800,000; September, 29,400,000; October, 31,500,000; total, 265,400,000 lbs.

The Anaconda payroll for October in Butte will total approximately \$1,672,264.23, which is \$112,264 in excess of the amount paid in wages for September. This company pays slightly more than half of the total mining payroll of the district and estimates place the total at close to \$2,500,000.

Figures are not available for the independent mines, but it is believed that these will average higher than for any other month of the year. The Clark properties will distribute as wages in excess of \$70,000 from the 6th to the 10th of the month. The Butte & Superior paid approximately \$267,000 on 10th. North Butte on 8th distributed \$166,169. East Butte will pay this month about \$150,000, pay day coming on 15th. Smaller companies in Butte will distribute approximately \$60,000 more. The October payroll is figured on the basis of a wage of \$4.50 per day in accordance with the sliding scale and this rate will prevail as long as copper is above 25 cts.

Unofficial figures of the Butte & Superior show that the October production was substantially larger than for September and that both zinc and silver values are considerably in excess of the yield for the preceding month. The two months are compared as follows:

Tons of ore milled, 54,450, Oct.; 50,150, Sept.; Zinc concentrates, tons, 14,800, Oct.; 13,650, Sept.; Zinc in concentrates, pounds, 15,600,000, Oct.; 14,500,000 Sept.; silver, ounces, 320,000, Oct.; 300,000, Sept.; recovery, 94.5, Oct.; 94, Sept.

NEVADA.

Goldfield.

The improved flotation plant of the Florence-Goldfield Co. is operating on 200 tons of copper-gold ore daily and effecting a highly satisfactory recovery. Practically all the copper is recovered, and from 85 to 90% of the gold and silver. Experiments are being conducted in expectation of increasing the gold extraction. The company is preparing to install additional machines of the Jones-Belmont type. In the southern part of the mine, at a depth of 530 ft., splendid ore is being opened and some of this is going to the flotation unit.

Sinking at the Silver Pick is proceeding rapidly and as soon as the quartz-zone has been penetrated extensive lateral work will be pushed. For about 200 ft. the shaft has been in this great mineralized zone, although occasional horses have intruded. It appears that a huge quartz channel has been intersected, and occasional high assays in gold and silver encourages the belief that the western end of Goldfield is destined to produce heavily. But until more development has been completed it will be impossible to determine the importance of recent disclosures.

The vein uncovered lately in the Jumbo Junior at a depth of 880 ft. is showing excellent ore, and the discovery is considered highly important. It has been opened for 60 ft. by drifts and is the full width of the workings. Assays

on the last few feet range from \$16 to \$30. A winze has been started in ore and values are steadily improving. It was in adjacent ground that the Jumbo Extension uncovered a deposit that yielded over \$2,000,000.

A new and promising vein has been uncovered at a depth of 700 ft. in the Blue Bull mine. It was tapped in a crosscut about 700 ft. east of the shaft and gives encouraging assays. Some water is showing but the pumps are easily taking care of the flow. Manager D'Arcy is arranging to extend drifts and raises on the ledge.

Groom.

This district, near Pioche, is evincing much activity and several companies are actively exploring and working new and old properties. The ores are largely silver-lead and of excellent grade. Several Ford trucks have been placed in operation, also Holt caterpillar tractors, for the hauling of ore from various mines to Indian Springs, from which point consignments are forwarded to smelters. The James Kelly property has passed into the hands of Utah people and shipments will be started shortly.

The Groom Southend Co. has been organized to work a promising group of claims in the south-end section of the main field. Work is to start at once and before the close of December the management expects to be shipping regularly. Several other properties are about to enter the shipping class.

Jarbidge.

Progress in the camp has been steady for the past few months, but without much outward show except in the town, where the tents are rapidly giving way to frame buildings. About 150 men are working in the mines and some 50 are working on buildings in the town.

A local company is being organized to pipe in the water from Bear creek for fire protection; less than a mile of pipe will give a pressure of over 200 ft.

The Long Hike Co. is opening up a large ore reserve. It has built a gasoline power plant on the river, and is putting in an electric hoist on the winze in the lower tunnel, which will be sunk to a depth of 500 ft. A boarding and bunk house is to be built near the tunnel. An inclined surface tramway is being built to take up supplies for the mine and boarding house, from the river. A Fulton Iron Works gasoline hoist is being installed at the top of the tram. A Delco electric light plant has been established at the office to furnish lights for the company buildings in the town.

Hedges & Donaghue have bonded the Ajax group of claims at the head of Bonanza creek to Tacoma parties, and are now busy packing in supplies for the winter work.

Las Vegas.

Another strike was made in Eldorado Canyon last week, when James German, Mike Fisher and Chas. Herman, leasers on the Lombard claim, side lining the Carnation, upon which the big strike was made recently, uncovered ore which it is believed will run as high as the ore taken from the Carnation claim. At a depth of about 20 ft. ore from the Carnation claim assayed \$3500 in gold and silver.

The machinery, consisting of compressor, drills, etc., for the Eldorado Empire Gold Mining Co., has been shipped from Los Angeles, C. E. L. Gresh having bought the equipment while there. Reports from the Empire state that the ore is getting richer as development proceeds. It is generally conceded that another big producer will soon be added to the list when development on the Empire proceeds a little further.

E. P. Jeanes arrived from Los Angeles last week, where he has been for the past 10 days on business connected with the Eldorado Enterprise Co. The management of the Enterprise Gold Mining Co. has been looking over the property with a view of installing machinery to further development.

A lease on the Lucky Jim mine has been given to Frank Hoine and Ike Allecock, who are planning to push development and resume blocking out ore which has already been exposed.

Rapid progress has been made by the Cliff-Era Co. during the past few weeks. The main working shaft has already reached a depth of 155 ft. with water still in evidence. It

is the intention of the management to carry the work on to the 200 level and cut the large vein which runs through the Cliff-Era property over 4000 ft.

Recent communications from prominent mining men in San Francisco indicate that an excursion is being planned to Eldorado Canyon in the near future. Interest is growing in mining circles and San Francisco stands ready to furnish financial assistance necessary to exploit the properties in the Eldorado district.

W. A. Scott, representing the Mining & Engineering World, is in Eldorado Canyon preparing matter for an article soon to be published. This number will include illustrations of interesting points, and portray activities, progress and development in this fast growing mining district.

It is announced by the Enterprise Gold Mining Co. that application for listing the stock on the San Francisco Stock Exchange has been made. It is the intention to have the stock called within the next few weeks.

NEW MEXICO.

Santa Fe.

Of the 78,485,760 acres of New Mexico nearly half is public land and 14,000,000 acres state land. Ranches cover 12,000,000 acres, somewhat less than 2,000,000 acres is cultivated, and less than 600,000 acres is irrigated. Of the irrigated area 200,000 acres belong to individuals or partnerships, 50,000 acres to commercial organizations, 300,000 acres to co-operative or community organizations, and 30,000 acres to Indians. The remainder is irrigated under government reclamation, and the area so served will be considerably increased when the lands below the Elephant Butte dam are utilized. One of the greatest mineral resources of New Mexico is coal, which occurs in the large fields west of Raton, at places near Cerrillos, about Gallup, and in several other areas. There are also valuable mines of gold, copper, silver, lead, and zinc. The total production of these metals in 1915, according to the Geological Survey, had a value of \$19,279,468, of which \$13,437,961 was copper, an output that gives New Mexico considerable prominence as a copper producer. The output of gold was \$1,461,005. The value of the coal mined in the state in 1915 was \$5,181,361.

Mogollon.

At the Pacific mine the haulage cable for aerial tramway to Socorro Co.'s mill was placed during week and the traction cable is now being installed. A good vein has been encountered in north drifts from 500 and 600 levels. The territory south of shaft will be opened later as present underground activities are up to limit of hoisting equipment.

The slime-carrying flume being built by Mogollon Mines Co. has been completed from Last Chance mine to the Maud S property, a distance of about 1 mile, and is now in commission. This will eventually be extended about 4 miles farther down canyon to present tailings impounding dams.

There are practically no idle men in camp and from different quarters comes the report of a scarcity of labor of all classes to a greater extent than has been noticeable for some time past.

OREGON.

Granite.

Algernon Del Mar is now mill superintendent at the Congar mine. The wooden pipe line, for the camp's water supply, has been completed and is now conveying water from Granite Creek to the property.

The Independence mine is to be unwatered for examination. The shaft is 200 ft. deep, and it will take 2 or 3 days to pump out the lower level. The examination is being made with a view of selling.

The Taber Fraction mine has been sold for \$60,000 to J. A. Howard of the Oregon-Idaho Investment Co., Baker, Ore. John Arthur in charge of the mine has a force getting the mine ready for operations.

SOUTH DAKOTA.

Custer City.

Through investigations and the direction of Prof. Dove, the Slavonian mine is now a financial success. Except for 4 or 5 men the property will be closed down during the winter.

In the Two Bit district there is considerable activity at both gold and tungsten properties. Leasers on the Monarch have opened good ore and are getting a shipment ready. Sasse and Wolfe are also getting ready to ship from their tungsten property. Among other properties which are being operated are the Wiswell, Brensahan, Buffalo, Gilt Edge, Smart, Washington, and the Zipp. At these mines both development and production is being carried on.

TEXAS.

El Paso.

The mineral exhibit at the recent International Soil Products Exposition held here attracted much attention on the part of visitors. Collections of ore from many of the mines of the southwest and Mexico were on exhibition. One of the features of the mining department was a modern assay office that was in actual operation by students of the Texas State School of Mines and Metallurgy. A large collection of ore samples, including many rare minerals, was also embraced in the State School of Mines exhibit. F. H. Seamon, head of the chemistry department of the school, and Prof. H. D. Pallister of the geological department were in charge of the exhibit.

There was also shown in this exhibit a framework of timbers that was placed in the mine by the Spaniards and which is still in perfect condition. The timbers are less than 4 ft. in height as the shafts driven by the Spaniards were only high enough to permit a man to crawl through them.

Included in the mineral display that was made by Grant county, New Mexico, and which was in charge of M. W. Porterfield of Silver City, were ore and water buckets of buffalo hides, used by the Spaniards in operating mines near Silver City in 1785. These ancient relics were discovered in the deepest workings of the mines of the Chino Copper Co. at Santa Rita, N. M. The buckets were used by the Spaniards when they worked the mines 131 years ago. They are not of rawhide, as rawhide is known today. They are shrunken and of a greenish color from the copper ore. The hair is still on the hide.

Burnet.

The Texas Graphite Co. has under consideration the enlargement of its mill, situated near here. It has enough graphite in sight to keep a mill of much larger capacity than the present one in constant operation. Dan McFarland, manager, returned to the property recently from California.

Terlingua.

The lower workings and mine equipment of the Chisos Mining Co. here which were recently damaged by fire, has delayed operations of that quicksilver property somewhat. Orders were immediately placed for new equipment and it is expected to be installed in a short time. The furnace of the company was not damaged by the fire.

UTAH.

Monticello.

F. F. Sanmon has charge of a group of claims north of here for Salt Lake interests which are producing radium. Calyx drills are being used to further explore the formation. A force of 15 men has been busy throughout the summer and during that time about 5000 sacks of ore, carrying 2% or better, have been piled. This ore is now ready for shipment.

Quantities of lower grade have been exposed by development which has been in progress for several months.

N. C. Christensen is installing a mill at the Big Indian Copper Co.'s mine for the treating of low-grade carbonate ores. It will have a capacity of 300 tons. The process provides for the leaching of the copper through the agency of a solution of sulphur dioxide. The metallic values freed from the waste rock are thrown out of solution when the sulphur dioxide gas is driven off as the sulphur is heated. The entire details of the process as well as the plans for the mill were completed in the metallurgical department of the Univ. of Utah before going on the property of the Big Indian company.

American Fork.

The main tunnel at Belorophon is 300 ft. in and a drift has been sent north, following ore. A distance of 50 ft. out the face shows 6 to 18 ins. of high grade. This is 100 ft. vertically underground. The ore is found along a shale-quartzite contact. The past few days some copper has been coming in. It is a black oxide speckled through the rock. The work now is in the big fissure.

The Miller Hill Exploration Co. has contracted for power and placed an order for machinery with which to drive their tunnel with increased speed into the mountain between the Dutchman and Pacific mines.

The tunnel is now in 670 ft. and has 800 more to go to cut the fissure.

The Alberta Mining Co. has been incorporated to work a group in Deer creek and Silver Fork. The officers are Ammon Mercer, president; S. H. Roundy, vice-president; who with M. F. Cowley, Nelson McCarty and David Davis form the board of directors. James L. Mercer will act as secretary. Mercer has had a force working all summer, and now has a 135-ft. tunnel that is nearing the contact which in the upper workings showed good values in gold, silver, copper and lead. In one of the workings a fine body of molybdenum was opened. Preparations are being made to continue work all winter. The company is capitalized for 600,000 shares, one-half of which is treasury stock.

Alta.

At Michigan-Utah in the Alta mine the crosscut from the Grizzly tunnel to the contact between the white lime and porphyry has encountered a body of copper-silver ore which will run \$75. When this ore was first struck it was 2½ ft. wide. The present face is 8 by 9 ft. and going down strong on the contact. The ore is being followed on the level. As soon as the dip of this ore is determined work will be commenced in the lower tunnel.

Beaver.

In a crescent from the drift on the 200 level of Beaver combination a good showing of ore was encountered. Buildings for the miners have been completed, a compressor installed, the winter's supplies laid in, and something like \$12,000 expended in the preliminary work in order that there may be no handicap during the winter in prosecuting developments. The miners will now drift both ways on the vein from the 200 level, while the sinking of the shaft will be continued.

Park City.

The Silver King Con. mill has been completed and is now in operation and the 10,200-ft. aerial tram will be ready soon. The new Thaynes tunnel is now in 800 ft. It has 14,000 ft. to go before it reaches its objective. The mine has several hundred tons of ore stocked.

Judge Mining & Smelting has opened ore on the 900 and will proceed to open ground between the 900 and 1200 levels in the Back vein. Ore was first opened up on the 1200 level. It has been followed along the strike 300 ft. Raises were run on the ore to the 900 level. Here the ore continues up. It is a high grade milling ore, much of the value being in zinc. The ore varies in thickness from 15 ins. to 15 ft. About 4000 ft. from the shaft a body of ore is being developed above the 1200. This has been followed 250 ft. Preparations are being made to extend the shaft to the 1900 level. At present it is down 1650 ft. It is the intention to raise from the 1900, which is open through the Daly West workings. All the steel work is completed and the machinery

is being installed at the mill. The electric equipment has been shipped and will arrive soon. The management is hopeful of completing the work by Jan. 1, 1917.

Eureka.

Smelters are now accepting 100 tons of siliceous ore daily from Iron Blossom. From the 1300 level of the winze in the north end of the mine a drift is being sent out for the copper deposit which has already been opened on levels above the 1300. It is the intention to drive to the ore at this point and then continue the work of sinking the winze, going down to the 1400. Within the next week or ten days the 1300 drift should be in the ore.

By Nov. 30 it is expected that Tintic Milling will be handling 300 tons. Six roasters have been added to the plant and two more are on the ground awaiting installation.

WASHINGTON.

Spokane.

The activity of the Anaconda Copper Co. in the Coeur d'Alene district has revived rumors that the corporation is contemplating establishing an electrolytic zinc reduction works in or near Spokane, and it is said that representatives of the Anaconda interests have been investigating the old smelter site three miles down the Spokane river with a view to purchase. C. Kelly, vice-president of the company, with members of his metallurgical staff was here several weeks ago investigating conditions, and they were here again recently checking their original preliminary survey of the situation.

The Anaconda has the Douglas mine, a complex lead-zinc property in the Pine Creek region of the Coeur d'Alenes, under bond for \$256,000, and the Douglas stockholders have extended the time of payment of the installment now due until March, 1917. It also has had ore buyers in the field for some time, endeavoring to secure contracts on zinc ores from other Coeur d'Alene companies. The Douglas group is extensively developed, exposing large bodies of commercial ore, and shipments now are being made regularly to the Anaconda's electrolytic plant at Anaconda.

The old smelter site on the Spokane river is regarded as an ideal location for an electrolytic plant. Transportation can be provided easily by extending the lines of the different transcontinental railway systems operating through Spokane, or by an independent electric system connecting with the steam terminals here. Current is available from the Washington Water Power Co.'s local plant and a big power station at Long lake, one of the greatest producers of electric energy in the west, and it is said that a satisfactory rate for energy has been agreed upon between the Washington Water Power Co. and the Anaconda officials.

An electrolytic plant here would not only draw from the zinc producing mines in the Coeur d'Alenes, but it also would result in greater development of zinc properties in different parts of northern Washington, the most of which now are dormant because of lack of treating facilities. The different railways radiating in every direction into the surrounding regions are easily reached from the numerous zinc holdings, and it is conceded that no better point could be selected for the establishment of such an enterprise.

Loon Lake.

Heavier machinery is being installed at the Loon Lake Copper Co.'s mine with which to carry on further development. For this work \$15,000 has been set aside. In speaking of the company's intentions Frank G. Crane, secretary-treasurer, says: "It is proposed to add three lifts of 100 ft. and to run out drifts on each level, starting the lateral work at the end of each 100 ft. A depth of 500 ft. will be attained. Encouragement for this work is given by the response of the shoot and its tendency toward expansion at the 200. The ore body is 50 ft. long above the level and 160 ft. on the floor, where a radical change in its form occurred. The shoot has a width of 3 to 7 ft. and has been stoped to a height of 33 to 35 ft. throughout. No return of less than 11% copper has been received on a shipment. The highest has been 13.75% and the average 12%. Six carloads of ore

have been shipped this month and another will probably be moved before the month ends. With 2 carloads shipped late in September 9 cars will have been sold within five weeks. New installations include a 50-hp. boiler, engine and a pump. The power to be generated will operate a 15-hp. hoist, the compressor, pump and ventilating system. It will be sufficient for a long period of prospective operation and was provided because the former plant was inadequate. Completion of development to the 500 is expected by spring."

Walla Walla.

B. Coyle, president of the Guelph Co., states that his company has purchased \$6000 worth of new machinery. "We have bought a 5-drill compressor and a hoist that will be efficient to a depth of 800 ft. This plant and an electric motor will be installed at a shaft in which a depth of 100 ft. has been attained by hand drilling. We expect to strike ore at the 200 point. The collar of the shaft is 250 ft. lower than the tunnel in which considerable work was done. Seven men are employed and two shifts will be engaged throughout the winter. Provisions for five months have been taken to camp.

WISCONSIN-ILLINOIS.

Highland.

No shipments of zinc ore have come from this camp in two weeks. Several large plants, however, are fully occupied and a fair tonnage of zinc ore lies piled up awaiting the buyer.

Linden.

Milwaukee-Linden Development Co. has disposed of 1000 tons of zinc concentrate to local buying concerns. This cleans up about the only reserve ore in this section. Fourteen cars of concentrates were delivered to separating plants last week, 537 tons. The Spring Hill Mining Co. with a new rig began operations the first of this week. Strikes of zinc ore are reported on the Gilman, Glanville, Optimo and Weigel properties.

Cuba City.

National Separating Works have been receiving raw zinc concentrate in quantity, 41 cars being delivered to the plant last week, 1716 tons being the best week's business yet reported for the plant. Shipments of high grade were normal, 9 cars in all, 343 tons. Locals were out of the running. Several new mills are being built in this section.

Miffin.

Poor management and failure to connect with ranges has resulted disastrously for the M. & A. Mining Co. operating the Big Tom property. Coker mines are running strong on strikes in new ground on both the Sunrise and Sunset lands. Stopes are being carried 74 ft. high. Shipments last week ran 10 cars, 9 going to the Mineral Point Zinc Co. and 1 car of high-grade to DePue. The Senator mine is shipping heavily under new management. Finishing touches are going on a new plant on the Yewdall lease for the Vinegar Hill Co. Drills have been successful for the Grunow and Lucky Six Mining Cos. Locals delivered 1 car of ore, mixed lots, to the furnace at Mineral Point, 38 tons. Montfort reported 1 car high-grade 55% wet concentrates from the O. P. David mine and a strong range on a turn to the north after going $\frac{1}{2}$ mile on a due east and west range.

Platteville.

Deliveries of zinc ore to track for the week ended Nov. 4 totaled 163 cars, all grades, 6508 tons; two cars of lead ore cleared, 77 tons. Shipments of pyrites fell off considerably, 828 tons clearing for the week. The gross recovery of crude ore for the week showed a gain, reports coming in for 5600 tons. Net deliveries to smelter, both refinery and mine run stuff, was 2677 tons. Seventeen cars of refinery product came from the Mineral Point Zinc Co. alone, 631 tons.

Prices showed decided improvement and gains were made over the prices of the week before, 60% ore ruling on a base of \$70 per ton, with premium grades bringing fair figures in advance of this. The range on medium and second grade ores was also raised to \$65, and much low grade ore cleared

as a result of heavy buying by nearly all of the local zinc refineries in the field. The reserve looked upon 30 days ago as a depressant has practically vanished and much relief is felt on account of the clean up. Lead ore was quoted at \$85 per ton, but producers showed no disposition to sell.

Among local producing mines the Hodge alone cleared 4 cars of raw ore to Cuba, 175 tons. High grade separator ore came from the Block-House mine, 4 cars, 160 tons, to American Zinc Co. and 2 cars to Eagle-Picher Lead Co., Collinsville, Ill., 80 tons.

Benton.

Seventy-one cars cleared here last week for a total of 5,480,000 lbs. Vinegar Hill Mining Co. took the lead with 11 cars from the Kittoe mine, 5 cars from the Martin mine and 6 cars from the Blackstone, all to Cuba, 910 tons. Two cars came from the Sally mine. New Jersey Zinc Co. sent 5 cars, 200 tons, to track from the Fox and 3 from the Penna-Benton mine, 126 tons. Frontier Mining Co. shipped 8 cars, 339 tons, with the Calvert mine failing to report; Fields Co. 7 cars to Grasselli, 283 tons; Indian Mound to Grasselli, 2 cars, 70 tons; C. A. T. and Champion mines 9 cars to Skinner roasters, 394 tons. High grade ore came exclusively from the Wisconsin Zinc Co., 5 cars to Hillsboro, 196 tons; Lanyon Zinc Co., 31 tons, and Sandoval Zinc Co. 3 cars, 107 tons. A new power and milling plant is complete for the Wisconsin Zinc Co. on the Longhorn mine and production is in order on a range fully explored in adjacent lands. This work of exploration continues with 8 drilling squads, and in several instances has been exceptionally prolific in finds of extensive zinc ore deposits. Surface tramways are being built at both the C. A. T. mine and Longhorn mines to connect new shafts in ore with the main power and milling plants. The Hird mine is now ready to begin production after much work in fighting water and cutting through wild ground. On the Grotkin lease another new 200-ton mill is being built for the Frontier Mining Co. on the Bull Moose range. Dividend No. 3, of the Wisconsin Zinc Co. for 2% on stock of record Nov. 1st was paid on that date. Frontier Mining Co. paid its regular monthly dividend of 2% on the first of this month.

Hazel Green.

The Kennedy reported on 2 weeks deliveries 10 cars, 399 tons, to Mineral Point, and Monmouth Zinc Mining Co., 1 car, 30 tons; Cleveland Mining Co. to Grassellis, 41 tons; Wisconsin Zinc Co., 3 cars, 90 tons, and Lawrence Mine, 2 cars, 80 tons. The new McMillan mine has not reported any shipments as yet.

Shullsburg.

A new power and milling plant is going up for McQuitty and Rodhams on the Rodhams mine. The Winkill is shipping and the Mulcahy mine, of the Oliver Mining Co., is shipping 3 cars of high grade separator ore weekly. New roasters are being installed in the separator plant.

Galena.

Vinegar Hill Mining Co. on the Graham shipped 9 cars last week, 381 tons. Much drawback was experienced on account of heavy overflow and the new pumps are raising 2000 gals. per minute. North Unity shipped 2 cars, 85 tons. The Federal mine had a clean up with 4 cars, 125 tons, and has been shut down permanently. The Birkbeck, a new producer, turned in 2 cars, 76 tons, and is going conservatively until the mine is fully developed. Galena Refining Co. sent 1 car high grade to Lanyon Zinc Co., 40 tons; Wisconsin Zinc Co. to La Salle 3 cars high grade, 120 tons, and to Hillsboro 2 cars, 80 tons.

CANADA.

BRITISH COLUMBIA.

Three Forks.

The Rambler-Cariboo Mining Co. has sold 1000 tons of concentrates stored at the property to the U. S. Zinc Co. for \$23 a ton. The product will average 31% zinc and 28 ozs. silver. Reports from the smelter have also been received stating that \$13,000 are due in settlements for lead-silver ore. Production of 1000 tons of zinc concentrates

monthly is possible, in addition to the regular lead-silver output, and it is probable that the entire zinc output will be taken by the U. S. Zinc Co., with the exception of a small amount for experimental purposes at the Anaconda Copper Co.'s new electrolytic reduction works at Great Falls, Mont. Shipments of the 1000 tons of concentrates sold will be made to its plant at Blende, Colo., as soon as cars can be obtained.

Trail.

In a report to stockholders of the Consolidated Mining & Smelting Co. of Canada, under date of Nov. 1, and signed by President W. D. Matthews, announcement is made that the share capitalization of the corporation is to be increased 25%, and each stockholder of record at the close of business Oct. 21 will have the right to subscribe at par for one share of the new issue for every four already held. The date of subscription expires Dec. 1, and 25% of the price, \$6.25, is payable on that date, and the subsequent instalments of equal amount are due Jan. 1, 1917; Feb. 1, and March 1. Failure to pay any of the instalments within the specified time renders previous payments subject to forfeiture, but provision is made for payment of the entire amount in advance, and such shares will be in rank for dividends on and after Jan. 1, while those paid for in instalments will not be eligible to share in disbursements until April 1. The directors have reserved the right to extend the times of subscription and payment in the case of stockholders residing outside of Canada who may not have received sufficient notice to enable them to exercise their rights. The purpose of the increased capitalization is to provide permanent capital to meet the expenditures involved in the enlargement of the smelter and metal refineries at Trail, and to finance more extensive development of the company's properties. Early in the current year the Imperial Munitions Board granted large additional contracts for high-grade zinc to the company, and, while a portion of the funds required for manufacturing the metal was advanced by the Canadian government, the corporation was compelled to finance construction of increased smelting and refining facilities. The report states also that the copper refinery has been enlarged; plants for the manufacture of hydro-fluosilicic acid have been installed, to render the refineries independent of foreign sources of supply, and considerable new equipment has been installed in the smelter, to bring it up to a capacity commensurate with the demands of the affiliated plants. It states also that mining operations have been extended and will be further extended, and that an option has been taken on an important copper property on the north end of Vancouver island, near tidewater. Development of the new holdings is under way, and still other groups are being examined, some of which undoubtedly will be taken over.

Illecillewaet.

With the completion of treatment on 15 cars from the Lanark Co.'s mine the method of concentration has been decided and a mill will be started at once, according to President Dornberg. "We will install at once a plant which will handle 75 tons a day and which will cost about \$25,000. Already we are putting up buildings to be prepared for winter. We have not let the contract for the mill, but my purpose here now is to do so. During the last few months we have shipped 15 cars of ore which have netted \$1000 a car in lead-silver ores. Much zinc-lead ore has also been opened up. In some places we have from 3 to 4 ft. of ore that goes 11% zinc and we have 10 ft. in width that averages 30% in zinc and is low in iron and lime, making it desirable for smelters. We hope to be able to ship our zinc concentrates to the smelter at Trail rather than to plants on this side of the line. We are sinking a shaft from the tunnel workings. This is down 75 ft. in 8 or 10 ft. of ore."

Kaslo.

It has been decided at the Utica to start a long drive to tap the ore bodies at depth of 350 ft. below the present workings. The work will start at once and be done by contract. The adit will be about 1900 ft. This will cost about \$25,000 and it is said the company has 35,000 surplus. Water shortage will compel the initial work to be done by

hand. In the spring a compressor plant is to be installed. It will get power from lower down the creek than where the intake for the existing plant is. It is not known definitely if it will continue shipments during the work on the cross-cut.

Sandon.

Machinery for the Slocan Star hydro-electric plant, including the Pelton wheel, left San Francisco Oct. 20 and is expected within 12 days. Everything is in readiness for installation. A steam plant is being used at the present time owing to shortage of water supply.

Clarence Cunningham has a bond on the Idaho-Alamo group and is now employing 12 men. At the Queen Bess he has a ledge of clean ore between No. 5 and No. 6 levels and above No. 5. Five men are employed in this mine on the ore and are taking out 7½ tons a day.

Nelson.

The California mine is now obtaining air for its drills from the Athabasca. Development in the 2nd level shows ore in the face becoming wider and increased in values. When the equipment for the air drills has been installed work will be resumed on No. 3 tunnel which is in 250 ft. and has to be driven 50 ft. more to hit the vein exposed in the 2nd level. In the drifts from No. 2 tunnel at the present time there is from 24 to 36 ins. of clean shipping ore in the face. Sixty tons of ore in the bins runs about \$45 to the ton. Between No. 2 and No. 1 tunnels 134 ft. of backs is given by the raise and the body has been proved for 300 ft. in length. Completion of No. 3 tunnel will give 205 ft. additional depth on this body.

ONTARIO.

Cobalt.

With 10 men under M. Cleveland the Shamrock made a good strike at the 300 level 15 ft. up in a raise. In the vein high grade silver and plate silver was encountered. The shoot is from 25 to 30 ft. in length and will run about 1700 ozs. to 1800 ozs.

With 30 men development is progressing at the Boston Creek Co.'s property. Work is being done through the R. A. P. shaft. A drift has been run into the Kenzie claim at the 100 level. The intention is to raise so as to connect with the Kenzie shaft. A diamond drill program is also under consideration.

Porcupine.

During the shut-down at Dome Lake reserves were increased about 25%. The new installations at the mill are now completed and the mill is treating 100 tons. The heads run about \$9. The new Hardinge ball mill is in place and about Dec. 1 the capacity should be increased to 200 tons. At present drills are working in four faces of ore. Lateral development is being pushed to the west on this level in expectation of cutting a new body 150 ft. from No. 2 stope of No. 1 vein.

A winze has been completed to the 900 level of Porcupine Crown and good ore is exposed. At the 500 level a diamond drill has been started. One hole is being put down at an incline, and is expected to cut the most promising veins at a depth of 1500 ft. About 500 ft. of work remains to be done in this hole.

West Dome Con. has started a new 4-compartment shaft. It is to be sunk some distance from the incline shaft. Raising and sinking will go on simultaneously. The crosscut from the old workings on the 300 level is being run to a point under the new shaft. From there a raise will be started to the shaft now being started.

Mazatlan.

El Tajo mine, at Rosario, 50 miles from Mazatlan, has been able to operate this year, though under great difficulties. Between 6000 and 7000 tons of ore per month are being treated by cyanidation, the crushing being by twelve 5-stamp batteries. Gold constitutes about two-thirds of the value in the ore, and silver about one-third. The bullion output, shipped out through the Port of Mazatlan to San Francisco, amounts to \$15,000 per month. J. D. Kislingsbury is general manager; Geo. A. Tweedy of Los Angeles being consulting engineer.

World's Index of Current Literature

A Weekly Classified Index to Current Periodical and other Literature, Appearing the World Over Relative to Mining, Mining Engineering, Metallurgy and Related Industries, in Four Parts.

—*Nevada Packard Mines Co.'s Mill*.—*Mg. World Oct.* 21 1916; p 707; pp 1*; 10c.

Gold Milling, Metallurgy, Etc.

See Mill and Milling, Metallurgy, Chemistry, Assaying, Etc.

Iron Ores and Mining

Rossmann, L. A.—*Screening Rock from Iron Ore*. [Operations as followed on Mesabi range Minnesota].—*E. & M. J. Oct.* 28 1916; p 787; pp ¾*; 25c.

Shellshear, W.—*Flotation at the Mt. Morgan Mine, Queensland, Australia*. [A paper read before the Aust. Inst. of Mg. Eng. Operations are described though tests are given more consideration].—*Mg. World Oct.* 28 1916; p 741; pp 3; 10c.

Iron and Steel

Belaiew, N. I.; Gondstow, N. T.—*Sur La Limite Elastique de L'Acier*. [From *Revue de la Soc. Russe de Metallurgie* on the elastic limit and other physical properties of steel under varying conditions].—*Metallurgie, French*; p 116; pp 33*; 75c.

Brearley, A. W.—*Structure and Properties of Steel Ingots*. [Abst. of a paper read before the Iron & Steel Inst., London. Shrinkage, contraction cavities and crystalline structure are dealt with].—*Iron Age Oct.* 26 1916; p 943; pp 4*; 30c.

Donaldson, J. W.—*Gases Occluded in Alloy Steel*. [A paper awarded the Carnegie Scholarship by the Iron & Steel Inst. The effects of different metals on the volume of gas is given].—*Iron Age Oct.* 26 1916; p 928; pp 3; 30c.

June, Robert.—*Insuluminum*. [Tests and description of a new ferro-aluminum alloy with great heat resisting properties].—*Pract. Eng. Nov.* 1 1916; p 924; pp 2*; 20c.

Portevin, M. Albert.—*Influence du*

Temps de Chauffage Avant la Trempe sur les Resultats de Cette Operation. [The influence of temperature changes with respect to steel and iron].—Metallurgie, French Feb. 1916; p 9; pp 70*; 50c.

— *El Acero Martin en el Mundo.* [The production of high-speed steels in the world compared with other classes of steel].—Revista Minera Aug. 24, 1916; p 402; pp 2; Sept. 1; p 417; pp 1¼; Sept. 8; p 428; pp 1¾; Sept. 16; p 437; pp 3¼; Sept. 24; p 453; pp 1½; Oct. 1; p 462; pp 2¼; \$2.10.

Iron and Steel: Foundry and Furnace Practice

Cooper, M. Stanley.—*L'Industrie des Sous-Produits du Coke et Son Rapport Avec La Fabrication du Fer et de L'Acier.* [Abstract from the journal of the Iron and Steel Inst. dealing with the by-product coke industry and the making of iron and steel].—Metallurgie, French Feb. 1916; p 79; pp 22*; 75c.

Portevin, M. Albert.—*Influence du Temps de Chauffage Avant la Trempe sur les Resultats de Cette Operation.* [The influence of temperature changes with respect to steel and iron].—Metallurgie, French Feb. 1916; p 9; pp 70*; 50c.

Silver

McCarthy, Morris.—*Mount Baker Mining District, Washington.*—Mg. World Oct. 28 1916; p 745; pp 1; 10c

— *Nevada Packard Mines Co.'s Mill.*—Mg. World Oct. 21 1916; p 707; pp 1*; 10c.

Silver Milling, Metallurgy, Etc.

See Mill and Milling, Metallurgy, Chemistry, Assaying, Etc.

Tin

Campbell, William.—*Recent Progress in Metallography.* [With some description the greater part is a bibliography of literature].—Amer. Inst. of Metals Adv. Copy 17; pp 63; 35c.

— *Union Tin Mining Progress.* [On production and general condition of the industry in South African fields].—S. Afr. Mg. Jnl. Sept. 16 1916; p 55; pp 1; 35c.

Tungsten

Aichino, Giovanni.—*Tungsteno.* [On the concentration and treatment of tungsten ores].—Ind. Chim. Min. & Met. Sept. 19 1916; p 273; pp 5; 35c.

Scott, W. A.—*Concentrating Tungsten Ores, Boulder County, Colorado.* [On milling methods and equipment in several of the more important plants of the district].—Mg. World Oct. 21 1916; p 697; pp 1¼*; 10c.

(II) NON-METALS

(A) FUELS

Coal Fields and Mining

Boulton, W. S.—*Study of Concealed Coal Beds.* [The presidential address to the British Assn. for the Advancement of Sci.].—Coal Tr. Bull. Nov. 1 1916; p 43; pp 4½; 25c.

Cady, Gilbert H.—*Coal Resources of District VI, Illinois.* [Describes the coals and formation of the district].—Ills. Geol. Surv. Bull. 15; pp 94*.

Fay, Albert H.—*Coal-Mine Fatalities in the United States, August, 1916.* [The information is mostly in tabulated form].—U. S. Bur. of Mines Report; pp 28.

Mullen, Patrick.—*New Mining Method*

in the Connellsville Region. [A paper read before the Engineers' Soc. of Western Pennsylvania].—Coal Age Oct. 28 1916; p 700; pp 2¼*; 20c.

Parr, S. W.—*Chemical Study of Illinois Coals.* [Gives the analysis and discussion regarding the same for a number of different samples].—Ills. Geol. Surv. Bull. 3; pp 80*.

Staples, Ernest H.—*Some Effects of the Master Folds on the Structure of the Bristol and Somerset Coalfields, England.* [A paper read before the Manchester Geol. & Mg. Soc.].—I. & C. Tr. Rev. Oct. 13 1916; p 1; Coll'y Guard. Oct. 13; p 699; pp 1½; 35c.

Coke

Burr, K. M.—*Safety in Coke Oven Operations.* [A paper read before the National Safety Council advocating the selection of workmen as a means for reducing accidents].—Coal Age Oct. 28 1916; p 709; pp 2*; 20c.

Cooper, M. Stanley.—*L'Industrie des Sous-Produits du Coke et Son Rapport Avec La Fabrication du Fer et de L'Acier.* [Abstract from the journal of the Iron and Steel Inst. dealing with the by-product coke industry and the making of iron and steel].—Metallurgie, French Feb. 1916; p 79; pp 22*; 75c.

— *Coke Production for Nine Months of 1916.* [From the Connellsville Courier].—Coal Tr. Bull. Nov. 1 1916; p 27; pp 1¾; 25c.

Petroleum

Brokaw, Albert D.—*Preliminary Oil Report on Southern Illinois.* [Describes areas tested and the geology of the formation with respect to oil deposits].—Ills. Geol. Surv. Bull. 35; pp 13*.

Deustua, Ricardo A.—*La Industria del Petroleo en el Peru Durante 1915.* [A paper read before the Pan-American Congress on the petroleum industry in Peru in 1915].—Inf. y Mem. Soc. Ing. Peru June 1916; p 117; pp 34*; 75c.

Lewis, James O.; McMurray, W. F.—*The Use of Mud-Laden Fluid in Oil and Gas Wells.* [Describes the system and other methods of details in drilling for the purpose of stopping waste of gas in drilling for oil wells].—U. S. Bur. of Mines Bull. 134; pp 86*; 25c.

(B) STRUCTURALS AND CERAMICS

Concrete

Chace, W. G.; McLean, Douglas L.—*Studies Regarding Concrete Mixtures Employed in Construction of the Shoal Lake Aqueduct.* [A paper read before the Canadian Soc. of Civil Engineers].—Canadian Eng. Oct. 26 1916; p 331; pp 3½; 35c.

— *Concreting in Cold Weather.* [Various special methods to be used on work being done in cold weather].—Portland Cement Assn. Sept. 1916; pp 15*; 35c.

III. TECHNOLOGY

MINES AND MINING

Surveying and Drafting

Molesworth, Guilford L.—*Pocket Book of Engineering Formulas.* [Information on civil, mechanical and electrical engineering work].—Spon & Chamberlain, N. Y.; book; pp 936*; \$1.50.

Weeks, Walter Scott.—*A Graphic Meth-*

od for Correcting Steel Tapes. [This article also appears in the Univ. of California publication. Curves, data and formulas are given].—M. & S. P. Oct. 28 1916; p 625; pp 3*; 20c.

Ore Genesis

Ball, Sydney H.; Thompson, L. S.—*The Southwest Virginia Lead-Zinc Deposits.* [The authors argue that the deposits were made by waters of magmatic origin].—E. & M. J. Oct. 21 1916; p 735; pp 2¾*; 25c.

Cady, Gilbert H.—*Coal Resources of District VI, Illinois.* [Describes the coals and formation of the district].—Ills. Geol. Surv. Bull. 15; pp 94*.

Drilling and Boring

Lewis, James O.; McMurray, W. F.—*The Use of Mud-Laden Fluid in Oil and Gas Wells.* [Describes the system and other methods of details in drilling for the purpose of stopping waste of gas in drilling for oil wells].—U. S. Bur. of Mines Bull. 134; pp 86*; 25c.

— *Recent Developments in Drilling Apparatus.* [Describes recent patents for equipment to be used with rock drills].—Mg. World Oct. 21 1916; p 705; pp 1¼; 10c.

Shafts and Shaft Sinking

Sayre, Edward A.—*Shaft Sinking Through Soft Material.* [A paper read before the A. I. M. E.].—Coll'y Guard. Oct. 13 1916; p 700; pp 1½*; 35c.

Mine Water

Young, C. M.—*The Chemistry of Mine Water.* [Brings out the chemistry of methods used to reduce the corrosive action of the water and it is pointed out that products from the water might be made to pay for the treatment].—Coal Age Oct. 28 1916; p 704; pp 4*; 20c.

Telephones and Signalling

— *Electric Signalling in Collieries.*—I. C. Tr. Rev. Oct. 13 1916; p 453; pp 1*; 35c.

Haulage and Conveying

Wolfe, D.—*Safe Transportation Underground.* [From the Lehigh Employes' Magazine].—Coll'y Guard. Oct. 13 1916; p 713; pp ½*; 35c.

Storage

— *Quarrying and Shipping Iron Ore.* [A description of the Broken Hill Proprietary Co.'s mines, Australia].—Mg. & Engg. Rev. Sept. 5 1916; p 308; pp 7*; 35c.

Accidents

Fay, Albert H.—*Coal-Mine Fatalities in the United States, August, 1916.* [The information is mostly in tabulated form].—U. S. Bur. of Mines Report; pp 28.

Rescue and First-Aid

Coldham, J. C.—*The Organization and Equipment of a Mine Rescue Station.* [A paper read before the Aust. Inst. of Mg. Eng.].—S. Afr. Engg. Sept. 1916; p 47; pp 1; 35c.

Jeremiah, Thomas.—*The Actual Worth of Oxygen Breathing Apparatus.* [On the use and what can be obtained with the oxygen helmets].—Coal Age Oct. 7 1916; p 577; pp 1½; 20c.

Paul, James W.; Wolfson, H. M.—*Rescue and Recovery Operations in Mines After Fires and Explosions.* [Detailed text on the subject for both metal and coal mines].—U. S. Bur. of Mines; pp 109; 35c.

Willcox, Fred H.—*Safe Practice at Blast Furnaces*. [Shows safe and unsafe way of doing things and has notes on some first aid].—U. S. Bur. of Mines Tech. Paper 136; pp 73*; 30c.

Safety

Burr, K. M.—*Safety in Coke Oven Operations*. [A paper read before the National Safety Council advocating the selection of workmen as a means for reducing accidents].—Coal Age Oct. 28 1916; p 709; pp 2*; 20c.

Wolfe, D.—*Safe Transportation Underground*. [From the Lehigh Employes' Magazine].—Coll'y. Guard. Oct 13 1916; p 713; pp ½*; 35c.

Rescue and First-Aid

Steidle, E.—*Oxygen Mine-Rescue Apparatus*. [A paper read before the International Assn. of Fire Engineers].—E. & M. J. Oct. 28 1916; p 797; pp 2¼; 25c.

Labor and Management

Varty, A.—*Officials' Reports to the Mine Manager*. [A paper read before the National Assn. of Colliery Eng.].—I. & C. Tr. Rev. Oct. 13 1916; p 448; pp 1½; 35c.

Sanitation

Watkins, J. A.—*Health Conservation in Steel Mills*.—U. S. Bur. of Mines Tech. Paper 102; pp 36; 15c.

Sociological

Jones, W. T.—*Main Island Creek Coal Co.'s Plant at Omar, W. Va.* [Deals with sociological and sanitation features as established by the company].—Coal Age Oct. 21 1916; p 682; pp 2*; 20c.

Production

Bancroft, J. Austen.—*Mining Operations in Quebec During 1915*. [A separate report on the geology of the zinc-lead deposits in Portneuf county is included].—Quebec Dept. of Mines; Report; pp 146*.

Boulton, W. S.—*Geology and Petroleum Resources*. [Abst. from the presidential address to the Geological Section of the British Assn.].—Petro. World Oct. 1916; p 489; pp 2¼; 35c.

Butler, B. S.; Loughlin, G. F.—*A Reconnaissance of the Cottonwood-American Fork Mining Region, Utah*. [Notes on the history and production are given, with a detailed description of the formation and operations].—U. S. G. S. Bull. 620-1; pp 62*.

Deustua, Ricardo A.—*La Industria del Petroleo en el Peru Durante 1915*. [A paper read before the Pan-American Congress on the petroleum industry in Peru in 1915].—Inf. y Mem. Soc. Ing. Peru June 1916; p 117; pp 34*; 75c.

McCasky, H. D.—*Quicksilver in 1915*. [Report by states and the United States on the production of the metal and market conditions].—Min. Res. of U. S. I. 11; pp 19.

Payne, Henry M.—*Mining the Frozen Gravels of the Arctic*. [A general account of operations, production, etc., in Siberia].—Sibley Jnl. Oct. 1916; p 2; pp 4½*; 30c.

Ryan, Edward.—*Biennial Report of the State Inspector of Mines, Nevada, 1913-1914*. [An account of the metal production by counties and separate descriptions of accidents].—Report; pp 52.

Smeeth, W. F.—*Annual Report for the Year 1914*. [Part I takes up production and general conditions of the industry,

while Part II is more of a geologic nature on several of the districts in the state].—Mysore Dept. of Mines and Geol.; pp 188*; \$1.75.

Yale, Charles G.—*Gold, Silver, Copper, Lead and Zinc in California and Oregon in 1915*. [Reviews the production by counties and in general].—Min. Res. of U. S. I. 10; pp 51.

Yale, Charles G.—*Gold, Silver, Copper, Lead and Zinc in California in 1915*.—Min. Res. of U. S. I. 10; pp 51.

—*Coke Production for Nine Months of 1916*. [From the Connellsville Courier].—Coal Tr. Bull. Nov. 1 1916; p 27; pp 1¾; 25c.

—*El Acero Martin en el Mundo*. [The production of high-speed steels in the world compared with other classes of steel].—Revista Minera Aug. 24, 1916; p 462; pp 2; Sept. 1; p 417; pp 1¼; Sept 8; p 428; pp 1¾; Sept. 16; p 437; pp 3¼; Sept. 24; p 453; pp 1½; Oct. 1; p 462; pp 2¼; \$2.10.

—*Rhodesia Output of Gold and Other Metals and Minerals, July 1916*.—Rhodesia Chamber of Mines Report; pp 6; 35c.

—*Tin Smelting Capacity of the World*. [Gives the possible production of tin from different companies' plants and from different districts].—Mg. Jnl. Sept. 23 1916; p 615; pp 1½; 35c.

—*Union Tin Mining Progress*. [On production and general condition of the industry in South African fields].—S. Afr. Mg. Jnl. Sept. 16 1916; p 55; pp 1; 35c.

Mining Costs

Gillette, Halbert Powers.—*Handbook of Rock Excavation Methods and Costs*. [Details regarding the different methods used in rock excavation, as drilling, explosives, etc.].—Clark Book Co.; book; pp 855*; \$5.

Scott, Herbert K.—*Manganese Ores of the Bukovina, Europe*. [A paper read before the Iron and Steel Inst.].—I. & C. Tr. Rev. Sept. 22 1916; p 312; pp 2¼*; 35c.

Tallant, J. D.—*Pillar Caving at the Braden Mines, Chile*. [A general description of the system and costs of operating].—Teniente Topics July 1916; p 13; pp 3*; 35c.

Williams, R. Y.—*Mine Ventilation Stoppings*. [Costs of construction and maintaining are given, with methods of constructing the stoppings, with special reference to Illinois fields].—U. S. Bur. of Mines Bull. 99; pp 30*; 20c.

—*Argentine Oil Industry Reconstituted*. [On laws, costs of operation, etc.].—Petro. World Oct. 1916; p 479; pp 1¼; 35c.

Accounts and Bookkeeping

Huac, A. J.—*Cost Accounting for the Clay Plant*. [Gives forms and description of part of an accounting system].—B. & C. Rec. Oct. 3; p 598; pp 1½*; Oct. 17 1916; p 709; pp 1½*; 70c.

Mining Miscellany

Jorgensen, F. F.—*Sprinkling Car for Mine Use*. [This tank car is designed so that the spray may be thrown in any direction].—Coal Age Oct. 7 1916; p 584; pp 1*; 20c.

—*Economics for Small Mines*.—S. Afr. Engg. Sept. 1916; p 46; pp 1¼; 35c.

MILL AND MILLING

Sampling

Fulton, Charles H.—*The Buying and Selling of Ores and Metallurgical Products*. [Methods of sampling and the different ways in which ores are settled for and penalized are explained].—U. S. Bur. of Mines Tech. Paper 83; pp 42; 15c.

Heath, George L.—*The Analysis of Copper and Its Ores and Alloys*. [Methods of analysis and assay for different products containing copper].—McGraw-Hill; book; pp 292*; \$3.

Woodbridge, T. R.—*Ore Sampling Conditions in the West*. [Excerpts from advance proofs of the U. S. Bur. of Mines Tech. Paper 86].—Mg. World Oct. 21 1916; p 703; pp 1*; 10c.

Crushing, Grinding, Etc.

Hoover, Theodore J.—*Concentrating Ores by Flotation*. [Third edition describing different processes, patents, litigation, history, etc.].—Mg. Mag.; book; pp 320*; \$3.75.

Jones, T. R.—*Pine Oil for Flotation Purposes*. [On experiments made to ascertain the proper destructive distillation of Norway pine for flotation oils].—Canadian Mg. Inst. Bull. Oct. 1916; p 882; pp 2; 35c.

Merrill, F. J. H.—*Recent Ball Mill Types for Grinding Ores*.—Mg. & Oil Bull. Oct. 1916; p 251; pp 4½*; 25c.

Shellshear, W.—*Flotation at the Mt. Morgan Mine, Queensland, Australia*. [A paper read before the Aust. Inst. of Mg. Eng. Operations are described though tests are given more consideration].—Mg. World Oct. 28 1916; p 741; pp 3; 10c.

Flotation

Pringle, L. B.—*Chart for Flotation Testing*. [A reproduction of the chart with explanation and formulas is given].—E. & M. J. Oct. 21 1916; p 749; pp 1¼*; 25c.

Shellshear, W.—*Flotation at the Mt. Morgan Mine, Queensland, Australia*. [A paper read before the Aust. Inst. of Mg. Eng. Operations are described though tests are given more consideration].—Mg. World Oct. 28 1916; p 741; pp 3; 10c.

—*Flotation*. [A discussion of the subject before the A. I. M. E. at the Arizona meeting, 1916].—M. & S. P. Oct. 28 1916; p 633; pp 6½; 20c.

—*Flotation at Mount Morgan, Australia*. [Abst. from the proceedings of the Aust. Inst. of Mg. Eng. Experimental work and the method as finally adopted].—E. & M. J. Oct. 21 1916; p 753; pp 2; 25c.

Concentration: Sorting, Sizing, Washing

Aichino, Giovanni.—*Tungsteno*. [On the concentration and treatment of tungsten ores].—Ind. Chim. Min. & Met. Sept. 19 1916; p 273; pp 5; 35c.

Bell, Robert N.—*Rich Gold Ore Found in Idaho*. [Reviews the deposits and recent findings in the Atlanta district].—E. & M. J. Oct. 28, 1916; p 783; pp 2¼; 25c.

Clyne, C. B.—*The Stoddard Mill—A Copper Concentrator*. [Description of a 100-ton concentrator operating successfully].—M. & S. P. Oct. 21 1916; p 598; pp 2½*; 20c.

Neal, Walter.—*The Manganese and Silver Problem*. [Notes on investigations made to find a satisfactory method for

treating silver-manganese ores].—*Jnl. Chem., Met. & Mg. Soc.* Aug. 1916; p 9; pp 9½; 35c.

Rossmann, L. A.—*Screening Rock from Iron Ore*. [Operations as followed on Mesabi range, Minnesota].—*E. & M. J.* Oct. 28 1916; p 787; pp ¾*; 25c.

Scott, W. A.—*Concentrating Tungsten Ores, Boulder County, Colorado*. [On milling methods and equipment in several of the more important plants of the district].—*Mg. World* Oct. 21 1916; p 697; pp 4¼*; 10c.

Amalgamation

Morse, E. C.—*Electrolytic Precipitation*. [Gives details of equipment and methods used in operating and testing a combination cyanide and amalgamation system as regards depositing the gold and silver with electricity].—*M. & S. P.* Oct. 28 1916; p 622; pp 2¾*; 20c.

Cyaniding

Bell, Robert N.—*Rich Gold Ore Found in Idaho*. [Reviews the deposits and recent findings in the Atlanta district].—*E. & M. J.* Oct. 28 1916; p 783; pp 2¾; 25c.

Morse, E. C.—*Electrolytic Precipitation*. [Gives details of equipment and methods used in operating and testing a combination cyanide and amalgamation system as regards depositing the gold and silver with electricity].—*M. & S. P.* Oct. 28 1916; p 622; pp 2¾*; 20c.

Neal, Walter.—*The Manganese and Silver Problem*. [Notes on investigations made to find a satisfactory method for treating silver-manganese ores].—*Jnl. Chem. Met. & Mg. Soc.* Aug. 1916; p 9; pp 9½; 35c.

Spaulding, C. F.—*Continuous Counter Current Agitation and Decantation*. [A mill constructed by the author is described besides others. Drawings are shown of plans and sections].—*Mg. World* Oct. 28 1916; p 3¼*; 10c.

Briquetting

Stillman, A. L.—*Coal Briquettes—Fuel of Future*. [A review of the past and present use of briquetted coal].—*C. Tr. Bull.* Oct. 16 1916; p 33; pp 2; 25c.

CHEMISTRY AND ASSAYING

Chemistry

Engle, W. D.; Gustavson, R. G.—*New Volumetric Method for the Determination of Cobalt*. [The method permits of the presence of zinc, cobalt, etc.].—*Jnl. Ind. & Engg. Chem.* Oct. 1916; p 901; pp 1¼; 60c.

Heath, George L.—*The Analysis of Copper and Its Ores and Alloys*. [Methods of analysis and assay for different products containing copper].—*McGraw-Hill*; book; pp 292*; \$3.

Mabery, C. F.—*The Relations of Chemical Composition of Petroleum to Its Genesis and Geologic Occurrence*. [A detailed discussion of the subject from a practical and theoretical view point].—*Eco. Geol.* Sept. 1916; p 511; pp 17; 60c.

Parr, S. W.—*Chemical Study of Illinois Coals*. [Gives the analysis and discussion regarding the same for a number of different samples].—*Ills. Geol. Surv. Bull.* 3; pp 86*.

Young, C. M.—*The Chemistry of Mine Water*. [Brings out the chemistry of methods used to reduce the corrosive action of the water and it is pointed out that products from the water might be made to pay for the treatment].—*Coal Age* Oct. 28 1916; p 704; pp 4*; 20c.

Analysis

Engle, W. D.; Gustavson, R. G.—*New Volumetric Method for the Determination of Cobalt*. [The method permits of the presence of zinc, cobalt, etc.].—*Jnl. Ind. & Engg. Chem.* Oct. 1916; p 901; pp 1¼; 60c.

Parr, S. W.—*Chemical Study of Illinois Coals*. [Gives the analysis and discussion regarding the same for a number of different samples].—*Ills. Geol. Surv. Bull.* 3; pp 86*.

METALLURGY

Thermic Metallurgy

Bell, Robert N.—*Rich Gold Ore Found in Idaho*. [Reviews the deposits and recent findings in the Atlanta district].—*E. & M. J.* Oct. 28 1916; p 783; pp 2¾; 25c.

De Lummen, Maurice V. M.—*The Roasting of Blends*. [From an article in the *Chem. Trade Jnl. & Chem. Eng., London*].—*E. & M. J.* Oct. 21 1916; p 741; pp 1¼; 25c.

Feild, Alexander L.—*A Method for Measuring the Viscosity of Blast Furnace Slag at High Temperatures*. [The methods of testing and some results, with a description of the apparatus used are contained].—*U. S. Bur. of Mines Tech. Paper* 157; pp 29*; 15c.

Lamb, Mark R.—*Copper Smelting at Naltagua in Central Chile*. [High prices of coke is causing a replacement of blast furnaces by reverberatory furnaces].—*E. & M. J.* Oct. 28 1916; p 777; pp 3½*; 25c.

Lomas, Garcia.—*Juicio Critico Sobre la Aplicacion del Moderno Horno Escocés a Nuestros Minerales de Plomo*. [On the application of the modern Scotch furnace and Spanish lead ores].—*Revista Minera* Aug. 24 1916; p 401; pp 2; 35c.

Smeech, W. F.—*Annual Report for the Year 1914*. [Part I takes up production and general conditions of the industry, while Part II is more of a geologic nature on several of the districts in the state].—*Mysore Dept. of Mines and Geol.* pp 188*; \$1.75.

Willcox, Fred H.—*Safe Practice at Blast Furnaces*. [Shows safe and unsafe way of doing things and has notes on some first aid].—*U. S. Bur. of Mines Tech. Paper* 136; pp 73*; 30c.

—*Tin Smelting Capacity of the World*. [Gives the possible production of tin from different companies' plants and from different districts].—*Mg. Jnl.* Sept. 23 1916; p 615; pp 1½; 35c.

Hydro-Metallurgy

Addicks, Lawrence.—*The Wet Treatment of Copper Concentrates*. [A paper read before the A. I. M. E. The ore is roasted and leached with sulphuric acid].—*M. & S. P.* Oct. 28 1916; p 630; pp 2¾*; 20c.

Neal, Walter.—*The Manganese and Silver Problem*. [Notes on investigations made to find a satisfactory method for treating silver-manganese ores].—*Jnl. Chem. Met. & Mg. Soc.* Aug. 1916; p 9; pp 9½; 35c.

Sims, Clarence E.; Ralston, O. C.—*The Electrolytic Recovery of Lead from Brine Leaches*. [The results of experimental work and operations with this method of procedure are given].—*Amer. Electrochem. Soc. Adv. Copy* 11; p 185; pp 15; 35c.

—*Copper Leaching, New Develop-*

ment in.—*Mg. World* Oct. 21 1916; p 706; pp 1; 10c.

POWER AND MACHINERY

Electricity

Year	49.690	23.470			

Difference in domestic and foreign prices explained by the fact that the New York quotations are per fine ounce; the London per standard ounce 8.925 fine.

Copper.—Foreign demand has been prominent, but domestic consumers who needed copper for early delivery outbid the foreign buyers at all times. Some foreign inquiries for first quarter metal have been in the market but no first-hand seller submitted quotations. The upward trend of prices, while especially vigorous in nearby metal, is spreading to forward deliveries. Already first quarter delivery is as scarce as spot, while the amount of business that is being booked for the second quarter means an early depletion of the supply for that period. And with this condition prevailing there are whispers that "something big" is brewing respecting copper for the second half of next year. It is known that leading domestic consumers are willing to place their second half requirements under contract, but greater interest is attached to the rumors that another tremendous foreign purchase is impending.

With a roaring bull market in copper prevailing only nominal interest is attached to statistics. October output is estimated at 172,000,000 lbs. Some producers may have sizable lines of copper with which to supply consumers whose inquiries were scaled down over the first quarter. It is noted that leading sellers have limited orders to what they regard as a margin of safety. If refinery output increases sufficiently so that an outturn of 200,000,000 lbs. is attained by January then some producers will have from 2,000,000 to 3,000,000 lbs. of copper a month over their actual sales. But this metal will be easily sold, as many consumers had their allotments reduced and have been promised full tonnages if production meets expectations. Detailed returns of the principal producers give the total output for the first 9 months of the year at 1,484,159,718 lbs.

The London market, after minor fluctuations, has begun to show a strong upward trend. Cables from London to leading producers indicate a serious shortage of electrolytic copper. Last week electrolytic declined to £142 10s, but at this writing is £2 higher. Standard copper holds steady at £124 for spot and £119 for futures. Stocks of standard copper in England on Oct. 31 totalled 3168 tons and fine copper in France 2290 tons, a decrease of 172 tons in the fortnight. The afloat from Chile amounted to 650 tons and from Australia 4000 tons, a decrease of 400 tons. Thus the total visible on October 31 was 10,108 tons as contrasted with 10,670 tons on Oct. 15.

Quotations for copper per pound at New York for the week ended Nov. 8 were as follows:

Tin.—The detailed tin statistics for October were distinctly unfavorable, there being shown increases in the visible supply and shipments of straits and Banka tin. Following their publication the market showed a tendency to recede, but when news of the sinking of the steamer Glenlogan, bound to London with 360 tons tin, was received, the market took on strength. The Glenlogan was destroyed by a submarine in the Mediterranean and bullish traders immediately took heart and advanced prices. When the news of the loss reached Singapore the market there jumped forward sharply with leading sellers refusing to quote. Based

on current market values the tin lost on the Glenlogan was worth about \$370,000. Importers here have not been informed whether any of the tin was for American account. Spot straits tin, which eased off to 41¾ cts., advanced to 42½ cts., and then at the opening of the current week went to 42¾ cts. Spot Banka recovered from 41¾ cts. to 41¾ cts.

Consumers displayed more interest in futures when the limits from the east came higher. The east offered April, May and June shipments at 41¼ cts. and the most recent limits have been at 41½ cts. Thus with September arrival held at 41½ cts. the spot price of 42¾ cts. is not considered high. For December delivery business was done at 42¾ cts. with January, February and March arrivals selling at 41¾ cts. The statistics at first depressed London and Singapore, but these markets recovered towards the close of last week with fair gains. At the opening of the current week Singapore advanced £3 10s to £187, thus restoring the premium over London.

The total visible supply on Oct. 31 was 17,415 tons, an increase of 1213 tons. Straits shipments amounted to 5868 tons against 3270 tons in September, while Banka shipments increased from 1263 tons to 2194 tons, American deliveries totalled 4556 tons, leaving stocks and landing of 3419 tons.

Quotations for tin per pound at New York and per ton at London and Singapore for the week ended Nov. 8 were as follows:

Nov.	New York		London.	Singapore.

Lead.—Business in lead has been very dull since our last report, but the strength of the market has not diminished in the least. With the turn of the month a few spot lots were offered at concessions by second hands, but producers, being solidly entrenched behind orders, adhered to their established quotations. Practically all of the producers are sold up for November. One producer has reserved a small tonnage with which to supply emergency requirements of regular customers. Dealers are not very large holders of November lead either. The very active buying that took place early in October has apparently given protection to all consumers. Therefore market factors do not look for any sensational developments.

It is stated that a resumption of business is not far off. One producer who is very close to the Canadian consumers who have in the recent past furnished the initial momentum to the market states that buying by the ammunition makers in the Dominion for December delivery will probably be started next week. Lead for December is quoted at 7 cts. New York, and 6.90 cts. St. Louis by independent interests. Spot lead in the outside market is available in small quantities at 7.02½ cts. New York and 6.85 cts. St. Louis. The leading interest has adhered to its price of 7 cts. New York and 6.92½ cts. St. Louis.

At London the market has shown no change, holding at £30 10s for spot and £29 10s for futures.

Quotations for lead per pound at New York and per ton at London for the week ended Nov. 8 were as follows:

Nov.	New York		London

Lead Ore.—In the Missouri-Kansas-Oklahoma district during the week ended Nov. 4 general conditions denoted a stronger market even though the top price remained at \$87, for the lower grades only ranged down to about \$83 against \$80 during the previous week. The week's production was 1,353,580 lbs., valued at \$57,380, and this brought the total for the year to date at 87,522,882 lbs., valued at \$3,629,257.

Zinc Ore.—A general increase in prices seems to again be coming as was noted by another increase in prices for ores during last week. The top price was \$80 per ton and this ranged down to \$70. The week's production of 12,350,420 lbs. was nearly 10% lower than that of the previous week and was valued at \$47,139. The total for the year was 561,968,240 lbs. valued at \$23,545,963.

Calamine.—Calamine shared in the boost of metal prices in the Missouri-Kansas district and sold for \$47.50 per ton as the top price, this ranging down to \$37. Production during the week was reported at 500,200 lbs., valued at \$10,802, and the total for the year was brought to \$30,389,585 lbs., valued at \$930,427.

Spelter.—Demand for spelter has once more become active and dealers have done a sizable business with prices showing a strong trend to higher levels. Business in prime spelter for delivery in the first quarter developed late last week and with the market responding quickly consumers have shown a desire to protect requirements. Producers assert that they are not selling very freely for forward delivery, but some selling by first hands has been noted. Galvanizers have again been the principal buyers, although some brass makers have been in the market.

From a study of the situation it appears that spelter will have up and down movements for months to come. Consumers stop buying as soon as the price passes 11 cts. and when the market is back to around 9½ cts. resume buying. This has been the case in the past 6 weeks. Producers, however, declare that they will obtain much higher prices by the

and with dealers disposing of their accumulations the producers will be in a position to send the price up rapidly as soon as demand develops.

Last week business in prime western was done at 10½ cts. to 10¼ cts., but this week selling has been from 10¾ cts. to 10.45 cts. St. Louis. Spot metal has advanced to 10.80 cts. New York and 10.65 cts. St. Louis. A few foreign orders have been in the market for brass special, but nothing worthy of special note has transpired. Spot brass special holds at 11 cts. St. Louis.

The London market has showed a gradual advance after an off movement last week. Quotations for spelter per pound at New York and per ton at London for the week ended Nov. 8 were as follows:

	New York.	London—	
		Spot.	Futures.
Nov. 2	10.55c	£52 10 0	£50 10 0

*For the first nine months; spot market nominal thereafter.

MISCELLANEOUS METALS.

Antimony.—Business in this metal has been small, with the market barely steady. Although sellers are not offering at concessions, it is stated that buyers could shade quoted prices without difficulty. Spot antimony is quoted at 13 to 13½ cts. duty paid. One Chinese producer who reports being well sold up is asking 14 cts. for spot. For November and December shipment sellers are asking 11¼ to 12 cts. in bond. There is a Canadian inquiry in the market, but otherwise little in the way of new business.

Tungsten.—The plant of the Atolia Mining Co. resumed operations on Nov. 1. The demand for tungsten has increased somewhat with sales of high-grade ore being made at \$18 delivered New York. Ordinary tungsten has sold freely at \$17. It is reported that a considerable foreign business is being negotiated, but these are not likely to mature for several weeks to come. Business is mainly for spot delivery and sellers report that holdings are now much smaller than they were a month ago.

Manganese Ore.—The market continues dull, with a general absence of new developments. Advices from Cuba are not very encouraging. Leading sellers report that demand is very poor and domestic ores are being sold at concessions. Agents of Cuban producers are asking 55@60 cts. for 40% metal contents. Some domestic ore is reported to have changed hands at a shade under 55 cts. Chemical ore is also quiet and unchanged at 4½@5 cts.

Quicksilver.—There is a fair demand for quicksilver, with the market remaining steady at \$80 per flask for spot virgin metal. Some sellers report that the placing of several large contracts for explosives may lead to higher prices, but leading factors in quicksilver do not look for an early advance.

Pig Iron.—The market is developed into a runaway affair. Birmingham iron has sold at \$20, Buffalo at \$25,

Lehigh valley at \$24, Virginia at \$25, these prices being for foundry grades. The average on bessemer and basic for October were the highest for a decade; bessemer average being \$23.6576 and basic \$20.3086. Buying has been tremendous in spite of the fact that many furnaces have withdrawn from the market. Many consumers have been caught uncovered for the first half. Selling for delivery in the second half of next year has been very active also.

Aluminum.—Business has been quiet both in the outside market on nearby deliveries and with the producers on 1917 contracts. Spot virgin ingots are quoted at 61@66 cts. On 1917 contracts the leading interest is quoting 35 cts.

Advancements and Present Status of Preferential Flotation

HENRICUS J. STANDER.

It is quite a hard matter for the practical mining man to readily obtain the required information, when he starts out on a preferential flotation proposition. Many of these mining men have not the time and opportunity to collect and sample out the rather scarce contributions on this subject, although they may be in great need of the same.

In Arizona there are now at least two small companies that are doing successful work on the separation of molybdenum and pyrite, while in Utah very successful results are being obtained in the separation of lead and zinc. Although I have perhaps been instrumental in helping along the experiments of some of these companies, one is not at liberty to publish any of their results or methods. The small company, and generally a leasing company in this instance, is beginning to be more and more reticent with regard to letting its neighbor know what it has succeeded in accomplishing.

Contributions to the literature of flotation, dealing with principles involved, and attempts made to set forth theories, with an endeavor to explain and elucidate such principles, are, of course, extremely valuable to the mining fraternity, and to the general development of the topic under discussion; yet there is an extremely large percentage of men directly connected with, or interested in, mining, that feel a keener desire to read and digest articles that bear directly on the real obstacles in the field of their operations. It is because of the great number of men belonging to this class, and also because of the frequency of the occasions on which such men have asked me to direct them to sources of information on preferential flotation, that this article has been prepared. And thus an endeavor has also been made to put all data in a form in which it can be of value to the practical operator.

"Preferential Flotation" is the term applied to that process by which one mineral is separated from another, both being minerals amenable to the flotation treatment. "Selective Flotation," on the other hand, means the flotation of a valuable mineral, in the presence of waste material. Making a froth concentrate

of galena and blende, from a lead-zinc ore, is a sample of selective flotation; but if two separate concentrates, one containing a high percentage of lead and the other a high percentage of zinc, are made, by means of two or more different treatments, the process would be "preferential."

There are at present leasing companies, operating on lead-zinc tailing dumps, that are making high-grade concentrates of lead and zinc, respectively. By the ordinary selective flotation process, they would be able to produce either a concentrate fairly high in the one metal, but with a very appreciable percentage of the other metal in the concentrate, or vice versa. In other words, they would not be able to make two separate concentrates, one of lead and the other of zinc. This is only made possible in the flotation field by a preferential treatment.

This process dates back to the year 1904. Cattermole, with regard to his preferential flotation process of 1904, says:

"The invention relates to the classification of the metalliferous constituents of ore which have been separated from gangue by oil or similar matter, and consists in fractionally removing the different constituents from the agglomerated masses by freeing the constituents in turn from oil, and thus obtaining them in a separable condition by the use of emulsifying agents of varying strengths and activity preferably in conjunction with an alkali."

His process is as follows:

"The metalliferous matter agglomerated by oil is mixed and agitated with a solution of an emulsifying agent, such as a soluble soap-alkaline oleate, for example, to which a certain proportion of soluble alkali, preferably caustic potash or soda, has been added."

He found that minerals vary in their affinity for oil employed in the above manner, and thus by heating the oily masses or granules in the first place with an alkaline emulsifying solution of a certain strength, the mineral of least affinity can be separated therefrom, and by increasing the strength or modifying the proportions of the breaking-down solution step by step, the various constituents can be thrown out in the order of their increasing affinities.

The Cattermole process involves one of the funda-

mental factors of flotation, although, in itself, it is a "bulk-oil" process. The Cattermole process is not of much direct practical value to us now, but it is mentioned because of the fact that Cattermole was one of the first to do work in the direction of preferential flotation.

So far the chief methods of preferential flotation can be classed into these three groups:

1. Roasting Methods.
2. The Use of a Chemical Solution.
3. Controlling Flotation.

(1.) The Roasting Process.

The roasting process was developed chiefly by Wentworth, Ramage and Horwood. This process really consists in the "deadening" of certain sulphides by a short and slight roast, while certain other sulphides, which may be present, remain unaffected by the heat. Ramage terms this "fractional roasting," while Horwood speaks of it as "preferential flotation." The Horwood process of preferential flotation is practically the same as the processes of Wentworth and Ramage.

In 1909 Wentworth patented his preferential flotation process, which depended on fractional roasting, and in the following year, Ramage, in explaining his own process of preferential flotation, says: "The principle of the process is founded on the combination of fractional roasting with chemical floating." He described the following three experiments as examples of his process.

(1.) The ore contains iron pyrite and chalcopryrite, with a content of 5% copper and about 35% sulphur. Preliminary roasting is necessary to deaden the pyrite, but must not be long enough to affect the chalcopryrite. The ore is then crushed to the required mesh and passed through a hot solution of acid sulphate of soda and nitric acid. The results of this is that the chalcopryrite comes up to the surface of the liquid, whereas the pyrite goes to the tailings. After the pyrite has been given an oxidized coating by the preliminary roasting, it is no longer so amenable to flotation as the copper sulphide, and by subjecting such a mixture of these two minerals to the hot-acid-bath flotation process, it is possible to float the chalcopryrite and allow the roasted pyrite to go to the tailings.

It is to be observed here that although in the above-given example, Ramage says that, after the roasting, the ore should be subjected to the hot-acid-bath process, it is not essential that this particular kind of flotation be used. The essential feature is that the ore must be given a preliminary roasting only sufficient to affect the pyrite, without oxidizing the chalcopryrite. The ore is then ready for flotation treatment. This preliminary roasting has simply made the pyrite less flotative, and thus making it possible to bring about the separation of the chalcopryrite and pyrite by two successive flotation treatments. A

few simple preliminary experiments will enable the operator to know exactly at what time to stop the roasting, as it is only a matter of seeing that the ore is not heated beyond a certain definite temperature. In the above instance the ore should not be heated beyond 600° C.

(2.) The ore contains pyrite, chalcopryrite and zinc-blende. It is roasted, but just enough so that only the pyrite is deadened, and this requires a temperature of about 600° C. By then crushing the ore and subjecting it to the flotation process, a concentrate of chalcopryrite and zinc blende can be obtained, the iron pyrite being left in the solution with the tailings. The concentrate of zinc and copper sulphides is then roasted up to a temperature of about 700° C., with the result that the zinc sulphide is decomposed; and by using a solution of dilute sulphuric acid, the zinc can be dissolved, and a separation of the zinc and copper thus brought about.

(3.) The ore contains cobalite, niccolite, chalcopryrite, pyrite and native silver. It is crushed and subjected to flotation, with the result that the silver goes to the tailings, whereas the other minerals come to the surface of the liquid in the form of a concentrate. The sulphides are then roasted to a temperature of about 800° C. The ore is again subjected to flotation, and this time only the chalcopryrite floats, as the other minerals have been deadened by this roast.

In 1913 the Zinc Corporation, Ltd., Broken Hill, Australia, adopted the Horwood process for separating the lead and zinc of its slime concentrates. Preliminary roasting, Horwood pointed out, makes it possible to float such a substance as sphalerite, whereas other sulphides, such as galena and pyrite, become deadened by the roasting and are then immune to flotation; so that the two latter substances will go to the tailings in the first treatment, while the sphalerite appears as a concentrate in the froth.

A report of the Zinc Corporation says:

"The Horwood process is being applied to a certain by-product from the zinc-lead concentrator. After a slight roast, this material is amenable to flotation, and yields on the one hand a fine zinc concentrate, and on the other a good lead concentrate. The application of the Horwood process has increased considerably the resources of the corporation."

(2.) The Use of a Chemical Solution.

In the Lyster process a preferential action is brought about by the use of a chemical solution. A frothing agent is used in a neutral or alkaline solution of the sulphates, nitrates or chloride of calcium, magnesium, sodium, potassium, or mixtures of these, or solutions of manganese, zinc, iron, acid sodium, or sodium potassium sulphate. In this process one mineral is floated in preference to another; for example, in a lead-zinc ore the lead is floated off in the first treatment; almost all of the sphalerite going to the tailings, and by retreating the tailings and using more oil, the sphalerite can be obtained in the form of a froth concentrate. It seems then as if the preferential

action really takes place in virtue of the fact that galena is more amenable to flotation than sphalerite, unless the chemical solutions employed brought about a marked change in the behavior of the sulphides, which does not seem possible.

This particular method of preferential flotation was further developed by Greenway and Lowry. Describing their process of 1914, they said that:

"If a salt of chromium (such as sodium bichromate or potassium bichromate) is introduced in solution in the circuit liquors, or if the material to be treated is subjected to the action of such chromium salts solution by digestion or otherwise, that the sulphides are affected in such a way as to leave certain of them amenable to flotation, whereby products are obtained relatively high in some sulphides on the one hand and in other sulphides on the other."

These inventors cited samples of a molybdenum ore carrying about 25% iron pyrite, of a copper ore containing 6.5% copper and 35% iron, and of a lead-zinc slime containing about 19% lead and 32% zinc. In each case the one mineral was separated from the other by the use of a weak, hot solution of sodium bichromate. In the case of the molybdenum ore, it does not seem as if the chromate is of any special use, since we know that molybdenite is more amenable to flotation than even galena; and in the ore carrying molybdenite and pyrite, the former is so much more easily floated than the latter, that a solution of sodium bichromate seems almost wholly unnecessary.

If an ore containing chalcopyrite and pyrite is ground sufficiently fine, the copper sulphides particles will constitute a much finer product than the pyrite, and it is because of this property of chalcopyrite to disintegrate into very fine flakes on crushing, that it can be separated from the pyrite by flotation. So that again it seems unnecessary to employ a chemical solution to bring about a separation of these two sulphides by the flotation process.

The chief point of interest in this process is that galena can be deadened by heating it with a weak, warm solution of sodium bichromate. A lead-zinc slime, containing 18.6% lead and 32.3% zinc, was put into a hot solution of 1% sodium bichromate; after the slime was left in the solution for half an hour, the liquid was decanted and the sulphides subjected to flotation; one pound of eucalyptus oil per ton of slime was used, and the froth formed contained 47.2% zinc and 6% lead, while the tailings produced contained 31.6% lead and 16.3% zinc. From this it is evident that the lead was made almost wholly unamenable to flotation; yet we know that galena is one of the very easily floated minerals, in fact more so than zinc sulphide. In this instance, a true preferential flotation was brought about by the use of a chemical solution. The sodium bichromate evidently deadens the galena particle, inasmuch as it oxidized the surface of the particle, whereas it does not affect the sphalerite.

With regard to the Bradford process for the treatment of mixed sulphides, we are told:

"The new process consists of treating ores in a medium that wets the zinc sulphide, and which does not wet the lead sulphide or pyrite, and therefore leaves the last-named sulphides floatable, while rendering the zinc sulphide temporarily immune to flotation. The lead sulphide or pyrite is thus obtained first as a float concentrate; thereafter the residues comprising gangue and zinc sulphide are treated for the separation of the zinc sulphide from the gangue.

"This wetting effect is procured by adding to an acid flotation solution a limited quantity of a substance that is decomposed by the said solution, and produces in this decomposition a reducing gas which is more or less soluble. Thio-sulphates, sulphites, and bi-sulphites are notably so decomposed in a solution of sulphuric acid with the production of such a gas (sulphur dioxide). With practically equal results, either the gas can be brought into it in a current, or added in solution. A similar result is obtained by means of another reducing gas, sulphuretted hydrogen, which may be introduced into the solution in the same way or may be produced in it by adding sulphides or polysulphides that the solution is capable of decomposing."

A considerable amount of work has been done on this particular method of preferential flotation, and in some cases results show that a true preferential action was brought about by the use of an acid solution of sodium chloride, or of zinc chloride of the right concentration, while in other cases organic substances afforded a means to produce a sharp contrast between two or more sulphides with reference to their amenability to flotation.

(3.) Controlling Flotation Method.

It is known to anyone at all familiar with the various flotation phenomena, that the percentage of extraction, by flotation, of a sulphide in an ore, depends on various factors. The degree of fineness of the gangue and of the mineral particles plays a very important role, and so also do some of the other variables, such as the amount and kind of oil or acid used, the time and speed of agitation, and the temperature at which the experiment is done. And furthermore we know that one sulphide is more floatative than another, a very important property in this particular phase of flotation.

In 1913 Nutter and Lavers made use of these different behaviors of sulphides under different conditions, and brought out their process for preferential flotation of minerals:

"It is a process for concentrating ores which consists in treating the crushed ore by a flotation process two or more times under different conditions to obtain froths or scums having the constituents of each in certain ratios of size, and thereafter subjecting the powdered mixture contained in each froth to a classifying step to separate the constituents."

According to the description of their process, the one sulphide can be separated from the other by correctly controlling certain conditions in the flotation plant.

The following is an example cited by the inventors: An ore containing galena, chalcopyrite and sphalerite, is crushed and admitted to the flotation machine. Using cresylic acid without any mineral acid it is possible to float most of the chalcopyrite, and a small quantity of the galena. So from this first treatment

a chalcopyrite concentrate is obtained, the residue being given a second treatment, and with the help of sulphuric acid, a galena froth-concentrate can be produced, most of the sphalerite being left in the tailings, from which it can then be removed. In case the ore contains only copper and zinc sulphides, a preferential action can be produced by the use of eucalyptus oil or creosol. No mineral acid is necessary, and a concentrate, containing most of the chalcopyrite and very little sphalerite can be obtained.

In a method where the separation of one mineral from another depends largely on certain conditions, the process becomes somewhat delicate, especially in the case of flotation, where there are so many conditions to regulate and control. Nevertheless, it seems as if one of the chief ways in which preferential flotation will be developed in the future is this method.

In summing up, I must say that of these three different methods of procuring a preferential action, the "roasting" and the "controlling flotation" methods have given better results in this country than has the "chemical solution" method. The actual flotation part in the roasting process is simple; the main thing to be worked out is, of course, the degree, or degrees, of roasting to which the ore is to be subjected. Once this is fully determined, so that the desired deadening effect, or effects, can be obtained, the problem resolves itself in getting the required successive flotation treatments, a matter which can easily be determined by experimentation.

Within the last year I have worked out an alkaline oil mixture which is now being used successfully at three preferential flotation plants. It seems as if, with careful experimental work, most of our troubles in preferential flotation will be solved either by the roasting method, or by the so-called controlling-flotation method.

Preferential flotation is sometimes also known as "differential flotation." It may be well, however, to speak of all methods for the separation, by flotation, of one mineral from another, or some minerals from other minerals, in the same ore, as "preferential flotation." It hardly seems necessary to employ the word "differential," as it may lead to confusion, rather than be of any help in the flotation literature. "Preferential" and "selective" ought to be terms sufficient to denote the two different flotation processes.

In reducing the size of pipes, say from 2 to 1 in., very often a 2-in. coupling and a bushing from 2 to 1 in. is used, the bushing screwing into the coupling, the 1-in. pipe into the bushing, while 2 to 1-in. reducer would do the work cheaper. One piece would answer for two, etc., or if an outlet was needed by means of a Tee, instead of using a 2-in. Tee with a 2 to 1-in. bushing in it, a Tee that has 2-in. ends and 1-in. branch (2x2x1), could be used. It costs exactly the same as a standard 2-in. Tee and by using it the cost of the bushing could be saved.

A Centrifugal Ore Separator.

Take ore or coal, carrying mixed impurities such as slate or bone, of a different specific gravity, mix them with large quantities of water and cause them to whirl rapidly in a conical tank, and separation will take place by virtue of centrifugal force and gravity. The heavier materials will be thrown farther out, and fall rapidly in a spiral, close to the surface of the cone. The lighter materials will be held longer in suspension and near the center of the cone. Frank Pardee, Hazelton, Pa., makes use of this principle in a new separator here shown. Suppose coal (light) is to be separated from slate (heavy). It is fed into the funnel (A). A powerful jet of water carries it through into the cone, near the top, admitting it tangentially. Coal, water and slate swirl about in the cone, falling spirally toward the open bottom. The slate, being the heavier, is carried outward and downward more rapidly and falls through the bottom, to be carried away

CENTRIFUGAL SEPARATION.

by the elevator shown in dotted line. The coal takes a more inward path and sinks more slowly, almost coming to a standstill at a level near the end of the pipe (E). By forcing another powerful jet of water through nozzle (h), vacuum is created, sufficient to suck water and coal up through (E) and discharge them to trough (e⁴) which has a perforated bottom so that the water runs into tank (F). The water is collected from the tank (F) and from the cone as shown by pipes and carried to tank (C), from which it is pumped into the nozzles and used over again.

Japan's Iron-Industry Commission.—The Iron-Industry Investigation Commission of Japan was authorized by the government on May 7 to conduct investigations as to the possible sources of ore and to devise plans for their acquisition. Other important matters to be looked into, according to Vice-Consul M. D. Kirjassoff of Yokohama, Japan, are the sorts of material the country most urgently needs and should try to produce first, measures for eradicating the clash of interests between government-owned and private enterprises and the means of accelerating the development of Japan's iron industry, because of its dependence on outside countries for iron and steel.

Mining and Milling at Robinson, Colorado

W. A. SCOTT.

The Progress Mining & Milling Co. is operating at Robinson, situated on the west side of the divide, between Leadville and Kokomo, Colo. The company has acquired 26 patented claims of the Wilson group, has leased the Iron Prince, Free America, Champion, Robinson and Col. Sellers, and has contracted for the production of Michigan group at Kokomo. This combination gives control of the Robinson contract for 3500 ft. on its northeast strike. This is a contact between a limestone footwall and a sandstone hanging wall. The ore occurrence is a replacement in limestone, the vein being nearly flat, having a dip of about 20°. The old workings are those of former individual holdings, and comprise Robinson tunnel, Wilson, Robinson, Felicia Grace and other shafts. The Robinson tunnel was driven 4400 ft. on the strike of the con-

has a depth of 1200 ft.; at its base is an 800-ft. incline on the contact. This shaft was being unwatered at the time visited, with a 500-gal. bailer; after all the water has been taken out, electric-driven pumps will be installed at the bottom. New air compressors are to be installed at Wilson and Robinson shafts, with the idea of making two main centers of operation. Both have steam hoisting machinery. The Felicia Grace shaft, below the mouth of the tunnel, has a steam hoist, and is being operated to get access to the ore on the Champion and others, having ore shoots off the main contact.

The mill, having capacity of 500 tons per day, is housed in an old building, purchased with the property. This plant is situated at the Wilson shaft. Electric motors for power are installed throughout, and a

PROGRESS CO.'S MILL, ROBINSON, COLO.

tact, attaining a vertical depth of 1000 ft. Workings from this tunnel established the existence of three or four ore shoots, on the contact, separated from each other by considerable distance; the ore in these shoots is highly mineralized, made up of iron sulphide, carrying lead, zinc, silver and gold, and very little gangue. The sections of the contact between the high-grade shoots consist of continuous, disseminated ore-bodies of low grade, much more silicious than the rest. The contact vein is 6 to 10 ft. thick. Development below the tunnel level was carried on by means of an incline, drifts from which opened the several rich ore shoots. At present, ore is being mined from stopes, both above and below the tunnel. Ore is also being mined on the 100, 200, 300 and 400-ft. levels of Felicia Grace shaft, which cuts other ore bodies. The Robinson shaft taps the contact at a depth of 600 ft. The Wilson workings, which are farthest east on the group, open ore shoots at a depth of 1040 ft., these being considered the downward extensions of the main ore shoots opened from the tunnel. The workings of Robinson and Felicia Grace shafts are connected with those of the tunnel, but the 200-ft. block between Robinson and Wilson shafts has not been opened. The Wilson

Sturtevant steam and hot-air heating plant has been installed. Heat is radiated from steam coils, and the atmosphere of the mill, kept at 60° F., is circulated by a fan in the plenum chamber, the entire volume of air in the building being changed every 15 minutes. Robinson is at an altitude of 11,000 ft., and proper heat supply and regulation are essential during the winter season. The coarse crushing is effected by Symons No. 5 and No. 3 crushers, and the fine grinding by a set of 42x18 Traylor rolls, this machine reducing the ore to 16 mesh. In this form it passes to 10 Butchart roughing tables, making a coarse lead concentrate. These table tailings are discarded, and the middlings are reground to minus 50 mesh in two 6 by 6-ft. ball mills made by Denver Engineering Works. This minus 50-mesh product is classified and the thickened material is treated by 12 Wilfley tables, making clean lead and iron products; also a zinc-iron middling which is reconcentrated on other Wilfley tables, making a clean zinc product. The iron-zinc middling from the last process is passed to three flotation machines manufactured and installed by Traylor Engg. & Mfg. Co. These machines are belt driven, and are in operation, turning out a flotation product

running 45% zinc. The table products carry 30 to 40% lead, accompanied by most of the silver and gold recovered, although the iron concentrates contain some silver and gold. The plan is to install other treatment plants, possibly including one for electro-magnetic separation of iron from zinc. It is stated that the capacity of the mill will be doubled next year.

Philip S. Smith, Denver, is president of this company; Ross D. McCausland is vice-president and general manager, with Thos. H. Teal as mine superintendent, and Roy Chapman as mill superintendent.

Field's Flotation Machines in Arizona.

The flotation mill being built for the Keystone Con. Mining Co., at Chloride, Ariz., is expected to be in operation before Dec. 1. This company is controlled by G. S. Holmes, Los Angeles, and W. O. Kay, John Pingree and others of Salt Lake. The plant was designed by the Fields Flotation Co. Utah Machinery Co., Salt Lake, has the contract for furnish-

Motor-Driven Four-Plunger Horizontal Hydraulic Pump.

The hydraulic pump illustrated is a recent addition to the extensive line of high pressure hydraulic pumps built by the Hydraulic Press Mfg. Co., Mount Gilead, O. It is of the horizontal, 4-plunger type and designed to fill the requirements for a simple, heavy duty hydraulic pump for supplying a large volume of water or other fluid against a high pressure.

This hydraulic pump is designed so that it may be equipped with 16 different sizes of plungers ranging from $1\frac{3}{8}$ to 5 ins. in diameter, advancing by quarter inches. The water cylinders are made of forged steel for the highest pressures. For the medium pressures, 1500 to 2900 lbs. per sq. in. inclusive, cast steel is used, and for the lowest pressures the cylinders are semi-steel. The pressures range from 9500 to 700 lbs. per sq. in., and the water capacity from 24 to 326

FOUR-PLUNGER HORIZONTAL HYDRAULIC PUMP.

ing and installing the equipment. The ore is to pass through a 9x15-in. Blake crusher, and then to a 5x6-in. ball mill, operating in closed circuit with an Aikens classifier, both made by Colorado Iron Works. The undersize of classifier is to be carried by a launder to a Fields flotation machine to make a rougher product, which is then passed to the cleaner cell of same type which will turn out a finished concentrate. As the ore consists of a silver, lead and zinc sulphide, the final concentrates will be passed over Wilfley tables for separating the lead from the zinc. The plan is such that there may be table concentration ahead of flotation, to collect the heavy lead product and eliminate a good part of the silica. In this case, the middling product would be sent to the flotation machines. The Fields rougher machine consists of a cell 30 ft. long, 3 ft. wide and 8 ft. deep. The air line runs across the top of the cell; the air is thence conducted by air hose to air lifts, built on 2-ft. centers, by which the solution is mixed and agitated, the pulp and water being drawn into ports at the bottom of the air lifts, then discharged at points 2 to 3 ft. above the surface of the solution through narrow apertures. By this operation thorough mixing and aeration is effected. The machine for cleaner work is similar to the rougher, except that it is smaller.

gpm. All sizes have bronze valve seats and bronze or nickel steel valves.

It is built for motor drive and requires 150 hp. to operate. The pump is equipped with a flexible shaft coupling for motor connection. Any 150-hp. motor having a speed of from 450 to 750 rpm. may be used. The speed of the crank shaft is 60 rpm. The stroke of the plungers is 16 ins., the two cranks being set at 90° so that a uniform flow of fluid may be obtained.

The construction of this pump is especially adapted to long service, being strongly built and well proportioned in every detail. At all points where the strain and wear is most severe, the parts such as main bearings, connecting rod ends, cross-head guides, valves and valve seats, are of easy access for adjustment and replacement. The frame or pump bed consists of two heavy castings securely bolted together. The cross-head guides and main bearing containers are machined in this frame. The pump occupies a floor space 18 ft. 8 ins. in length by 6 ft. 10 ins. in width.

While the illustration shows the pump equipped with a spur gear and pinion, the pump is just as easily equipped with a herringbone gear and pinion.

The Use of Signboards and Signals in Mines

D. J. PARKER* and E. STEIDLE.†

The more favorable accident reports of recent years of mining companies, of state mining departments, of compensation insurance companies and of the mine accident statistical department of the Bureau of Mines, emphasize unquestionably the importance of adopting every precaution or device, however simple, which may insure greater protection to the underground worker.

This paper has been written primarily with a view to increasing safety in mining operations, i. e., to draw attention to the need of sign boards and signals in mines, and particularly to suggest a set of danger and safety symbols which might be adopted by the mining fraternity and thereby be made universal for all mines.

In May of 1913, over 3 years ago, this same subject was discussed in Technical Paper 67 of the Bureau of Mines, entitled "Mine Signboards." However, no definite action has been taken in the matter by any particular mining company, mining district, or organization of mining men.

Use of Sign Boards.

History is antedated by the use of signs and symbols. It is a universal custom to place sign boards at street crossings in our cities; also to place warning signs at railroad crossings, dangerous excavations, etc. Costly electric display signs are now widely used in advertising. In fact, there are few conditions in the activities of man that do not embrace the use of sign boards.

If such signs as those above outlined are so commonly used on the surface where man has the benefit of the light of day, surely there is even more necessity for direction and warning signs and symbols in mines where there is little or no light. The Bureau of Mines pleads with all mine operators for the thorough and systematic posting of underground workings with sign boards marking dangerous places and conditions and pointing out the way to safety in cases of disaster. It is true that many operators post their mines, but the problem is not worked out systematically.

The Specific Problem.

To most captains and foremen, long acquaintance with underground workings make the sign board necessary. These men may, therefore, not readily see why any one else should require such guides. However, the fact that the average miner is generally of foreign birth or recent descent and almost a total stranger to the plan of the underground workings, is proof of the necessity of sign boards. This is especially true in the larger mines where hardly a shift passes that one

or more of the miners is not lost. The fact must not be lost sight of, too, that statistics prove that many accidents occur due to the negligence of well-experienced miners who have become somewhat hardened to danger.

There is a large floating class of labor throughout most of the mining districts of the United States. Moreover, the working places of the men in some mines often change from day to day, as the coal or ore is worked out, so that even a miner thoroughly acquainted with the plan of a particular section of the mine one week may find himself completely lost the next. Here surely a system of mine sign boards would guide the miner, no matter how strange or changed the workings might look to him. Such guides not only save many steps in the miner's daily work, but are of the greatest value to him in time of disaster, where even the coolest headed and best acquainted man may become panic-stricken.

Sign Boards.

The selection will depend on the type of the mine and, to a certain degree, on the class of miners employed. The size of the boards and letters will depend on the position which they shall occupy in the mine, the most logical viewpoint and the illumination being, of course, taken into consideration. The color scheme should be black letters on a white background.

Need for a Universal Set of Symbols.

The bureau also advocates the universal adoption of a set of nomenclature and symbols. This not only because non-English speaking labor is largely employed, a class which requires guidance in the matter of protecting themselves from accidental injury, but also because mine workers are generally of transient habit, and finally because the men are frequently changed from one portion of a mine to another with the dangers of which they are possibly unfamiliar. It is evident that a universal set of danger and safety symbols would soon become so impressed upon the mental vision of the worker, English speaking or whatnot, that wherever or whenever he might see a standard symbol he would understand intuitively its meaning and act accordingly. These symbols, if accepted universally, would in time be equally as significant to the illiterate as is the sign of the Red Cross to the armies and navies of the world. Under such conditions the danger symbol, for example, would be regarded by fair thinking men, judges, or juries, as a sufficient warning of danger.

Universal Symbol of Danger.

Red is the color in general use to indicate danger, and there appears to be no good reason why this color

*Mining Engineer. †Asst. Mining Engineer. Published by permission Director Bureau Mines.

should not be used in mining. It is recommended that a circle filled in solidly with red, making a red ball, and painted on a white background 12 by 20 ins. in size, be adopted as the universal symbol of danger. No wording whatever should be inscribed on the red disc, but appropriate words to designate a particular source of danger may be printed on the white background. (See sample on exhibition.)

Universal Symbol of Exit.

Green is the general accepted color to indicate caution and this color can be used in mining for the same purpose. The universal symbol of exit should be a plain, green arrow on a white background, 8 by 20 ins. in size. This symbol may or may not be accompanied by word or words printed on the white background to indicate any particular exit.

Universal Symbol Indicating Ladderway.

It is recommended that a green ladder on a white background, 8 by 20 ins. in size, indicate a ladderway or stairway (required for coal mines in some states). This symbol may or may not be accompanied by words or numbers printed on the white background to designate the mine working to which the ladderway leads.

Discussion of Proposed Symbols.

Standardized symbols should never be used to indicate any other notice, or, in other words, convey any other meaning, than that originally specified. For example, the "arrow" should be used only in pointing the mine exit. If it is desired to use an emblem to point out direction in the mine other than exit a "hand," or other appropriate emblem, should be used.

The arrow should be plain without tail. In poor light and at a distance an observer might not on first sight distinguish between the spearhead and the tail. This criticism of the arrow's tail has been raised many times by miners.

The color scheme is adaptable to home-made sign boards or rolled steel signs in baked enamel. Furthermore, these colors will show up clearly in illuminated signs. Ground glass makes an excellent white background and sets off to advantage either red or green colors.

Practice tests were made by the authors underground with signs made up in different combinations of colors, and the color schemes above suggested appeared to be most efficient in every particular; also white, red, green and black paint are easily mixed, are durable and are readily retouched.

The background for all mine sign boards should be white, because this color is easily soiled and is, therefore, more likely to be washed and retouched without delay when warranted. Letters or symbols in white on a dark colored background is not preferable, for the reason that the smallest area and most important part of the sign board would be that part of the board most quickly soiled and subsequently obliterated.

Sign Making.

In the case of a small mine, the engineers could design, to any size that is desired, a set of letters, number and symbols, or a pattern of the sign itself, on stiff, durable cardboard which could be cut out, forming stencils or sign patterns, as the case might be. With the use of these forms all signs could be painted quickly. A brush, a bucket of paint, a set of stencils, a few feet of plain lumber, a little time and patience and a complete set of mine sign boards could be had at little cost. From time to time sign boards should be washed of their accumulated dirt and the letters repainted. If properly cared for these sign boards should last many years.

In case of a large company, regular sheet copper or tin stencils or sign patterns can be purchased and used almost indefinitely. There are manufacturing companies which make enameled, steel signs. The letters and colors of enamel are fused on rolled steel which makes them indestructible. Where signs are purchased in quantity it is intimated that enameled, steel signs can be purchased as cheaply as home-made signs can be prepared and they will surely outlive the home-made sign.

Mine Signals.

Pages might be written on mine safety signals and shaft signals. Two safety signals will be discussed in this paper, principally because they are relatively new, simple and should prove exceptionally practicable. On first thought these safety signals may not be given due consideration, but we must not forget the fact that often the simplest safety device proves in reality the most effective. A common accident in a coal mine is where a miner traveling a haulage road steps into a manhole to let a trip go by, and unconscious of a second section, steps out into the roadway and is run down. The miner's eyes and ears are occupied with the first trip and he is not aware that a second section follows the first trip. Why not tie a cowbell to each underground motor. No two bells are of the same tone, and particularly where there is a variance in size. The ring of a cowbell is not sharp, nor does it ring loud enough when the motor is moving slowly in making up a trip or distributing cars, to drown out the signals of the snapper.

In metal mines it is not practicable to employ a station tender at each level. A miner will often extend his head out into the hoisting compartment, when the cage is above his level, to ascertain whether or not the cage is in motion. Place a cowbell under each cage and its ring will be clearly audible for several levels when the cage is in motion.

The mining law of states where mining is a principal industry, provides for a uniform code of shaft signals for the type of mines in that particular state. It is hardly to be expected that a standard code could be established that would entirely suit the conditions obtaining in all kinds of mines. The authors have not made a complete survey of the subject of shaft sig-

nals and with this apology will not commit themselves further on the subject.

In conclusion the Bureau of Mines desires to urge in the strongest language the thorough and systematic posting of mines with suitable sign boards, and particularly the immediate adoption by the whole mining fraternity, of a set of universal danger and safety symbols and the color scheme to be employed in preparing all signs and symbols. At some time there

must be concerted action in the matter, and if the question is left open for indefinite consideration, years may pass before anything satisfactory to everybody is selected. Why not, as a beginning, adopt the symbols and color schemes outlined above? There appears to be no reason why one or all of these symbols cannot be used in every mine in the United States; they will at least serve as a foundation upon which a final and complete set can be built.

G-E Miners' Lamp Approved by the U. S. Bureau of Mines.

Two improved forms of G-E miners' lamp have been recently approved by the Bureau of Mines (Approval Nos. 13 and 13-A, Schedule 6-A).

"Form C" has a case of drawn and folded sheet steel while the "Form D" battery container consists of $\frac{1}{8}$ -in. aluminum alloy casting, 91 per cent pure aluminum. Otherwise the lamps are identical.

The cap lamp is a steel shell lined with fibre insulation and contains the reflector of porcelain enameled steel and phosphor bronze spring contacts rigidly mounted. These latter hold the Mazda lamp bulb in such manner that it is shattered and expelled from the contacts by a blow that would be only sufficient to crack or chip the glass bulb as usually mounted. This prevents the heated filament coming in contact with inflammable gaseous air.

Double steel hooks electrically welded together and riveted to the shell provide means for attaching the lamp to the miner's cap. The cap lamp is waterproof and weighs about four ounces. The weight on the cap is about six to eight ounces, depending on how the lamp and cable are worn.

The lamp is a $\frac{1}{2}$ candle power wire-drawn Mazda with a guaranteed life of 300 hours. It has two contact bases, and a single filament running straight through the bulb together with the reflector produces a well diffused illumination at an angle of 130 degrees.

A 43-inch cable connects the lamp to the battery. This is ample for the unrestricted movement of the miner. It is double twisted, strand copper, rubber coated, individually, laid together and the whole rubber coated. The weight is about 8 ounces. This construction gives a strong, light, flexible, non-kinking cable, of low resistance. Protection at each end is afforded by steel spring armor, double at the battery and single at the lamp. The cable is fastened in the lamp and battery cover entrance bushings by rubber packings secured with lock nuts. It will stand a very heavy strain without loosening or putting undue strain on the terminals of the conductor. The case for the "Form C" is of two pieces of drawn sheet steel folded and electrically welded with horizontal corrugations

on the front. The cover is of cast aluminum in one piece including entrance bushing and hinge-pin. When the cover is closed phosphor bronze spring contacts on the inside engage the terminal studs of the battery at three points on each stud insuring perfect contact with maximum contact surface. These contacts are mounted on fibre insulating blocks riveted to the cover and exert a constant pressure on the studs, preventing loose contact or movement of the battery in the

G-E ELECTRIC MINERS' LAMP.

case. The cover locks with a simple, rugged, self-acting, double latch lock that unlocks with a key. Tempering is impossible without detection.

The case for the "Form D" is of aluminum alloy, $\frac{1}{8}$ th inch thick, in a single piece with hinge slot, belt straps and parts which are engaged by the lock. Otherwise it is identical with the "Form C."

Both forms have approximate outside dimensions

of thickness 2", height 6½", and width 5". Total weights are, "Form C" 4 lbs. 7 ozs., "Form D" 4 lbs. 13 ozs.

All metal parts are finished with a semi-transparent acid proof, baking varnish which gives a very serviceable and pleasing gray finish.

The battery is an "Iron-clad oxide" (iron-clad positive plate and "oxide" negative). It is guaranteed to give service for not less than 10¾ hours per charge throughout a period of two years. The plates are contained in a medium hard rubber, non-spillable case, ribbed vertically for strength and sealed with a special vent and filling plug. The cover is so constructed that the pressure of the contacts on the terminals strengthens the seal. All parts of the entire outfit are interchangeable. No gas is generated on discharge and explosions are therefore impossible.

Automatic charging racks are not part of the equipment but can be furnished to take care of any requirements. Each battery space on the charging board is provided with the proper resistance unit so that regardless of the number of batteries on charge the proper current is automatically maintained. The phosphor bronze spring contacts are of such form and arrangement that the battery cannot be inserted incorrectly. The proper polarity is absolutely necessary to secure contact. A single motion of the hand places the battery on the charging board and automatically cuts it into the charging circuit.

The advantages of this outfit are summed up as follows:

Ignition of mine gas is impossible.

Neither battery nor lamps can be short circuited.

The battery gives a full steady illumination for the entire shift.

Failures except as the result of accident are impossible.

It will operate submerged in water.

Safe, durable, efficient and easy to wear.

The light cannot be extinguished except by intentional disabling.

The outfit may be sealed so tampering will be rendered visible.

Ralph T. Mishler of Pomona, Calif., in his new oil flotation concentrator, repeatedly agitates the pulp, in the presence of air or other gas, each period of agitation being followed by one of quiescence, during which the concentrates rise to the surface and the gangue settles. The agitation is also carried on at a point in the concentrator where it is under the pressure of a considerable height of pulp, obtaining the advantage of expansion of the air bubbles as they rise to the surface.

In a mill where there are several elevators a number of belt clamps should be provided. During a period of general repair this allows quick work. They should be of different sizes according to the widths of the belts.

A Self-Dumping Wet Screen.

Maurice Peterson, who is superintendent of a concentration and flotation mill in Pioche, Nev., has devised a revolving wet screen, which, in addition to providing large capacity, has the features of being automatically self-dumping and self-cleaning.

The plan and side views show a vertical shaft carrying a framework upon which sectional screens (10) are mounted. Situated above the screens are two feed chutes (15), through which the crushed ore is fed continuously. The pipe (17) feeds water and

A SELF-DUMPING WET SCREEN.

air in a spray upon the ore as it falls upon the screens. The slimes and crushed material are washed through the screen by the force of the jet, the screen section at this point traveling in a horizontal plane.

It will be noted, however, that the outer end of the screen section (10) travels on wheels which follow an undulating track. After each screen section receives its batch from the chute, and the fines are washed through, the outer end of the screen comes to the dip in the track and, following down it, the screen section is tipped outwardly, dumping from its surface the coarser ore pieces which will not go through the screen and consequently need re-grinding.

TYPICAL OF THE NORTHWEST COUNTRY.

Northwestern Country Tributary to Spokane is a Great Mineral Producer.

J. E. DUFF.

By the end of 1916 mining companies, both coal and metal, operating in the northwestern territory will have distributed dividends amounting to \$13,828,920 for the year, and will have disbursed during their existence \$97,804,786. This estimate is based on the presumption that those corporations now sharing profits with their stockholders will pay the regular established rate of monthly and quarterly disbursements for the two remaining months of the period, and that those that have been in the habit of presenting their members with extra payments as Christmas gifts will continue the custom. This is an increase of \$3,268,860 over 1915.

Providing that this estimate is correct, mining companies in the Coeur d'Alenes and immediately adjoining territory in Montana and in eastern British Columbia will have divided among their stockholders during the year \$1,152,410 monthly, and they will have created and caused to be distributed in trade and investment channels not less than \$69,144,600, as the difference between gross income and net profits is expended for labor, equipment and supplies. This means that in the last 20 years the mining industry has brought into existence not less than \$500,000,000 of new wealth, dug from the hills and mountains of the intermountain regions of the northwest.

The most of this gigantic sum has been distributed in the districts where it was secured, the major part of it going into the coffers of the tradesmen of the different supply points or back into development of non-productive properties, but a small part of it going out of the country in the shape of purchase payments of equipment and machinery that can not be secured except in eastern manufacturing centers.

Operating costs are also being gradually reduced by the establishment of smelting enterprises in the

mining centers, such as the Granby Co.'s plants at Anyox and Grand Forks, B. C.; the Consolidated Mining & Smelting Co. of Canada at Trail, B. C.; the Northport Smelting & Refining Co. at Northport, Wash., and the new \$1,000,000 smelter being constructed by the Bunker Hill & Sullivan Co. at Kellogg, Idaho. The operation of these mammoth reduction works in the mining territory is resulting in keeping more of the wealth created by the companies circulating in the northwest than is generally supposed, as the enlarging of their activities results in increased payrolls and the employment of more men in allied industries, such as the collieries in western Canada, which supply practically all the fuel and coke required by the smelters; the manufacturers of building material and machinery that provide housings for the workmen in the different camps and equipment for the mines, mills and smelters, and the railway corporations that provide transportation for the ore from the properties to the reduction works, lime and coke to charge the furnaces and carry the finished product to the market centers, besides creating a demand for more men in the banks, mercantile establishments and other enterprises that profit, both directly and indirectly, from mining activity.

Of the wealth that is created by the mining industry in the immediate northwestern territory \$10,666,568 of the year's earnings are credited to the Coeur d'Alenes, which also is entitled to credit for \$61,558,714 of the grand total, while British Columbia contributes \$2,951,583 for the year and \$16,578,911 to the aggregate from its metal producing companies and \$210,769 and \$3,442,124, respectively, is contributed by coal and coke companies operating in western Canada provinces. Of the \$16,225,037 that was paid by the inactive metal companies, including those that have been absorbed by other corporations or dis-

INTERSTATE CALLAHAN PROPERTY, NINE MILE DISTRICT, IDAHO.

solved, the greater portion was from concerns that operated in British Columbia.

Among the Coeur d'Alene companies first place goes to the Hercules, which owns and operates the Hercules mine, at Burke, Idaho, rated as the premier silver producer of the west. This is a partnership and not a stock concern, and its earnings can only be estimated, but information from reliable sources places the net profits at \$250,000 monthly, or \$3,000,000 for the year, and it is believed that this estimate is conservative, as production during the period was greater than ever before and lead and silver prices higher than for any time since the property assumed a rank among important producers.

Second place is held by the Consolidated Interstate-Callahan Co., which owns and is operating the Interstate-Callahan and other groups of lead-silver-zinc properties, comprising approximately 150 claims, in the Nine-Mile district of the Coeur d'Alenes. This corporation, which inaugurated dividends in April, 1915, already has paid three quarterly dividends of \$1.50 a share, or \$2,092,455, and is certain to pay at least that much during the current quarter, which will make the disbursements for the year \$2,789,940, or \$6 a share on the issued capitalization of 464,990 shares at \$10 each, making the total payments \$5,347,385, or \$11.50 a share. Recent official reports state that the Interstate-Callahan Co. has not less than 4 years' ore in reserve at the prevailing rate of production, approximately 5600 tons of zinc concentrates and 400 tons of lead concentrates monthly, and it is officially stated also that the company can pay dividends of 10% annually with spelter at 5 cts. a pound.

The Hecla Mining Co. is credited with the third largest yearly payment, \$1,550,000, presuming that it will continue to pay 15 cts. a share for the remainder of the period, as there is every reason to believe that it will, as production has been increased since it leased the Union mill from the Federal Mining & Smelting Co., and a further increase is contemplated when the 200-ton addition to its own mill at Gem, now under construction, is completed. This will bring the milling facilities up to 950 tons daily, provided the Union plant, which treats 350 tons, is maintained in service. Hecla paid at the rate of 10 cts. a share monthly on its 1,000,000 shares at 25 cts. each in January, February, March, April and May, but in June the disbursements were increased to 15 cts. a share, at which

level it is believed they will be maintained so long as lead and silver prices remain at or near the prevailing quotations.

The Bunker Hill & Sullivan Co. holds fourth place in the tabulation for the year, credited with \$1,473,750, an estimate that is based on the presumption that it will pay but the regular dividend of 20 cts. a share in November and December. Extra dividends of 20 cts. a share, or \$81,750, were paid in March, April, May, June, July, August and September, but none was declared in October, leading to the belief, although no official announcement was made, that earnings in excess of dividend requirements for the next 2 months will be diverted to the surplus fund, to finance operations at the new smelter until the enterprise is self-sustaining. There is a possibility, however, that further extra payments will be made during the year. Bunker Hill & Sullivan takes first rank among Coeur d'Alene companies for total disbursements, having \$18,162,750 to its credit.

Caledonia ranks next to the Bunker Hill & Sullivan, accredited with \$912,750 for the year, having paid 3 cts. a share monthly to date, except in January, when but two cts. were distributed, and there is no doubt but the November and December payments will be equal to those of recent months. Search for the faulted orebody is being continued on the Keating tunnel level, but so far without success, according to recent announcement by Stanly A. Easton, general manager of the company, who also is president of the Caledonia Co., in which the Bunker Hill corporation is the controlling factor. In 1917 it is believed that the Caledonia Co. will be able to pay but 2 cts. a share, even though metal prices remain firm, unless exploration in the Keating tunnel results in locating the faulted ore. In fact, the management has officially announced that a reduction in the dividend rate is probable unless the lost vein is recovered.

There has been no increase in dividend payments by the Federal Co., which has paid three quarterly disbursements of \$1 a share, or \$120,000, on the preferred stock. The same amount probably will be disbursed during the current quarter, but no extra declaration is anticipated. The Federal properties, except the Morning mine at Mullan, which now is the principal producer, are said to be nearing exhaustion. The Iron Mountain mine, near Superior, Mont., purchased several months ago for \$110,000, has been

HERCULES MINING CO.'S PROPERTY, BURKE, IDAHO.

closed down, and also the Frisco mine near Gem, Idaho, also a recent acquisition. The Frisco mill has been sold to the Tamarack & Custer Co., for \$150,000, and as soon as a clean-up can be made at the mine it is said that it will be abandoned, at least temporarily, and there is reason to believe that the suspension of operations will be permanent.

The Success Co. suspended dividend payments in July, when 3 cts. a share was distributed. Similar payments were made in January, February, March, April, May and June, and 2 cts. a share special dividends was paid in April. The Success officials refuse to make any statement as to the financial standing of the company or the physical condition of the property, and as a result not even a prediction of the resumption of dividends can be made safely. The company now is involved in litigation with the Alameda Co. over alleged trespass on Alameda ground and the extraction of Alameda ore, and it also is in controversy with some of its stockholders, who, it is claimed, were refused access to the corporation's books and records.

The Stewart Co. paid no dividends to date in 1916, and it is not probable that any payments will be made. The management has announced that the Stewart mine practically is worked out, and efforts now are being made to secure new properties.

There were two new dividend payers added to the list during the year, the Tamarack & Custer, controlled by the Day interests, which owns and operates the Consolidated Tamarack & Chesapeake and the Custer holdings in the Nine-Mile district, and the Intermountain, organized several months ago to take over the old Amador mine, near Superior, Mont. The Tamarack & Custer made two payments, aggregating \$71,050, but the company is not shipping now, pending installation of an aerial tramway nearly 3 miles long, connecting the workings with the recently purchased Frisco mill, and it is not probable that any declaration will be made during the remainder of the year.

The Intermountain Co. will pay its first dividend, a half cent a share on its issued capitalization of 1,621,894 shares at \$1 each on October 20; another of equal amount has been declared for November 20 and it is believed that a similar disbursement will be made in December, according to an official of the company. The Intermountain Co.'s new mill, of 150

tons daily capacity, now is operating, producing an exceptionally good grade of concentrates, and the product is under contract to the British Columbia Copper Co. for treatment in its smelter at Greenwood, B. C., for a freight and treatment charge that is said to assure satisfactory profits. It is said that a several years' reserve of ore has been blocked out, and that soon the dividend rate will be increased to 1 ct. a share monthly.

The Granby Co., owning and operating properties in Alaska and different parts of British Columbia and smelters at Anyox and Grand Forks, B. C., already has announced its fourth quarterly dividend for the year, \$2 a share, or \$299,970, payable Nov. 1 to stockholders of record Oct. 14. This gives it first place among the British Columbia companies with disbursements of \$1,049,894 for the 12 months. For the first two quarters the payments were \$1.50 a share, but the rate was increased to \$2 a share, or 8% annually, in August, and it probably will be maintained indefinitely on this basis, as earnings and production are greater now than at any period in the corporation's history.

The Cons. Mining & Smelting Co. of Canada, with mines in northern Washington and eastern British Columbia and a large smelter and refineries at Trail, B. C., also has announced its full complement of dividends for the year, the last having been paid Oct. 1. No special disbursements by this concern are anticipated, as surplus earnings are being devoted to financing construction and equipment of the Trail plants, which eventually will be the most important of the kind in Canada, as refineries sufficient to handle the entire copper, gold, lead, silver and zinc output are being installed.

The Standard Silver-Lead Co., practically an exclusive Spokane corporation, owning and operating the Standard mines and mill at Silverton, B. C., will pay its regular monthly dividend of 2½ cts. a share, or \$50,000, each month in the year, and there is probability of an extra payment of equal amount in December. The company's earnings have been reduced in recent months because of zinc concentrate shipments having been held to the minimum, 500 tons monthly, but an effort is being made to dispose of the stored zinc product and the profits may be increased

to the normal sum by such a sale. The company's property is in better physical condition than ever before, recent discoveries of high-grade lead-silver ore in the upper tunnels of the Alpha claim having materially increased the reserves.

The Hedley Co., operating the Nickel Plate mine, a gold property, at Hedley, B. C., has paid three quarterly dividends of \$60,000 each, and undoubtedly will pay another of equal amount in December. Earnings for the year probably will be greater than ever before, but extensive development of the property is under way and a cyanide treatment system is being installed, both of which will be paid for out of the operating income.

The Mother Lode Co., operating in the Sheep Creek region, near Nelson, B. C., paid its initial dividend, \$137,500, in January, but no declarations have been made since, and no further payments are anticipated this year.

The Rambler-Cariboo Co., also a Spokane corporation, owning and operating the Rambler-Cariboo mine and mill at Three Forks, B. C., has paid \$87,500 to date in 1916, but the officials will not say whether or not further payments will be made this year.

The Le Roi No. 2, an English company, which owns and is operating the Le Roi No. 2 group at Rossland, B. C., has paid nothing this year, and, because of the European war, it is probable that this corporation's dividend record will be blank for 1916.

Western Canada coal and coke companies have paid \$210,769 to date in 1916, but owing to labor troubles, it is not believed that any further payments will be made during the period. This is problematical, however, and they may yet contribute to the year's total.

Why Diesel Engine Crank-Shafts Fail.

The engineer in charge is primarily responsible for the life of the crank-shafts of Diesel engines and simple precautions will prolong the period of usefulness indefinitely. A number of failures cited by recent authorities have been attributed to lack of alignment of the main bearings, which generally resulted from unequal wear of the several shaft bearings, although this same result was brought about in some cases by negligence in the erection of the engine, or to defective foundations in some of the older ones. A 4-cylinder engine is most likely to suffer shaft breaks, with the 2-cylinder types having heavy fly-wheels, a close second. The shafts almost always fail through the throw arms, the crack starting at the center and working outward. With the 4-cylinder engine the throw arm nearest the flywheel fails in most cases and this is also true of the 2-cylinder units. Either throw of the single-cylinder type may fail and with a 3-cylinder engine, which is the least likely to be affected, the failures are equally divided between the two end throws.

Dr. John Scott Haldane.

Dr. John Scott Haldane, the noted English physiologist, recently delivered a number of scientific lectures at Yale University, New Haven, Conn., and Johns Hopkins University, Baltimore, Md. Dr. Haldane took enough time from his lectures to visit the Pittsburgh experiment station of the Bureau of Mines. He expressed much interest in the various investigations that are being carried on in behalf of the miner

DR. HALDANE WEARING THE GIBBS APPARATUS.

and put on and wore the new Gibbs oxygen breathing apparatus which is now undergoing severe tests by the rescuers of the bureau. In fact, Dr. Haldane made the statement that although the apparatus had certain defects, which might be modified, it is one of the best apparatus that has yet been devised.

Illustration shows Dr. Haldane wearing the Gibbs oxygen breathing apparatus at the experiment station of the Bureau of Mines, Pittsburgh, Pa.

There were more strikes and lockouts in the United States in the 6 months ended June 1 than in entire year of 1915, according to Bureau of Labor Statistics. Between Dec. 1 and June 1, 1432 labor disputes were reported, while during 1915 the number was 1405. In May alone 396 strikes were started. Building and metal trades showed greatest strike activity, with mining next, followed by longshoremen and freight handlers, and clothing industries. Machinists started 44 strikes. Pennsylvania and New York had most labor disputes, Ohio ranking third, New Jersey fourth, and Massachusetts fifth.

Taking Care of the Men at the Mines. Texas Sulphur Deposits Are Being Actively Developed.

A good night's rest in clean, comfortable quarters makes a world of difference in a man's efficiency. The mine operator who recognizes this not only gets the most out of his men, but he is able to keep the good ones longer. The poor man is bound to be a floater,

MINERS' HOUSES OF TENNESSEE COPPER CO.

always; the good man moves along until he finds a place that suits him.

Observe in the illustration the bunk houses of the Tennessee Copper Co., at Copper Hill, Tenn. They are commodious, well-built and located amid sanitary surroundings. The interior view shows the Tiger steel bunks that are used. In this one room there are 300 double-deckers, capable of caring for 600 men. They

INTERIOR BUNK HOUSE, TENNESSEE COPPER CO.

are equipped with comfortable springs, and the frames are braced so as to be perfectly rigid. The upper bunk is sufficiently low for convenience in getting in and out, while there is ample headroom for the man occupying the lower one.

The Tiger bunks are made by Haggard & Marcusson, 1112 West 37th street, Chicago, Ill.

Fuel at most metal mines costs more per ton than at any other market, and by fact of location is often of inferior quality.

With certain kinds of coal, a series of check dampers, properly installed, will make a large saving in the coal bill.

The manufacture of sulphuric acid is now being carried on in Texas on a commercial scale of considerable magnitude. The Sugarland Manufacturing Co., which recently constructed a sulphuric acid plant at Sugarland, at a cost of about \$300,000, is now making regular shipments of the refined product. One of its largest recent consignments of sulphuric acid consisted of five tank carloads, all of which was destined to supply the urgent needs of a large fabric dyeing plant in New England. The raw sulphur for the plant at Sugarland comes from the sulphur mines of the Freeport Sulphur Co., near Freeport, Tex., situated about 60 miles south of Sugarland. A direct railroad connection between the two places was recently obtained by the construction of an extension of the Sugarland railroad, which is owned by the same interests that control the sulphuric acid plant and the large sugar refinery at Sugarland.

It is announced that the large sulphur deposits, situated in western Texas, particularly in the vicinity of Orla and Toyah, will be turning out big quantities of sulphuric acid in a very short time. Several companies are now installing equipment for mining the sulphur and manufacturing sulphuric acid in those localities. The Michigan Sulphur Co. and the New Orleans Sulphur Co., both of which have large sulphur holdings in that part of the state, have begun preliminary operations. They have already made some shipments of the sulphur and are preparing to greatly broaden the scope of their development work.

The large sulphur deposit situated in the vicinity of Fort Stockton, Tex., is being prospected by the Calumet & Arizona Copper Co. with the view of mining the product and manufacturing sulphuric acid. Large quantities of sulphuric acid are required for leaching copper, and it is for this use that the company is preparing to engage in its manufacture. The demand for the acid for copper leaching purposes is so great that some of the smelters have installed plants for extracting the product from the fumes that come from their plants.

It has long been known that native sulphur existed in enormous quantities in different parts of Texas, but it is only of late years, particularly since the big advance in prices of the refined product and its acid content, that the utilization of this natural resource began to assume big proportions.

The sulphur near Freeport is obtained by the Frasch method of forcing steam into deep wells and converting the product into liquid form and bringing it to the surface by powerful pressure. The underground deposit of sulphur near Freeport is said to be probably the largest yet discovered anywhere in the world. The deposits in western Texas are upon and close to the surface and they cover large areas of the desert region.

What the Mining Companies are Doing

October Copper Productions.

The production of copper by various companies is given below, comparing with previous months and years:

ARIZONA COPPER CO.				
	1916.	1915.	1914.	1913.
January	3,632,000	3,474,000	3,100,000	3,100,000

Nevada Con. Co., Nevada.

The third quarterly report of the company, just issued shows that production of copper amounted to 24,585,393 lbs., as compared with 24,091,021 lbs. the previous quarter. The following shows the production the three quarters of 1916:

Lbs.		Lbs.		Lbs.	
Jan.	6,157,862	Apr.	7,716,101	July	8,537,231
Feb.	6,436,853	May	7,723,148	Aug.	7,688,014
March	6,565,559	June	8,651,772	Sept.	8,360,148
Totals.	19,160,274		24,091,021		24,585,393
Av. mo. prod.	6,386,758		8,030,340		8,195,131

During the quarter 1,020,546 dry tons of Nevada Con. ore averaging 1.68% copper were milled, as compared with 1,094,879 dry tons averaging 1.57% copper for the previous quarter. Of the tonnage milled, 84% was supplied from the pits and 16% from the underground workings of the Ruth mine. In addition to the above 16,775 dry tons of Gironx Con. ore were milled during the quarter.

The cost of copper produced, including Steptoe plant depreciation and all charges except ore extinguishment, and after crediting all miscellaneous earnings was 8.67 cts. per pound, as compared with 8.51 cts. for the previous quarter. Excluding the item of depreciation the cost was 8.01 cts. as compared with 7.78 cts. for the previous quarter. The outcome is figured on copper price of 23,883 cts. per pound for the quarter, and 24.959 cts. for the first 9 months of the year. No copper available for delivery remains unsold.

There was a surplus for the quarter of \$1,901,740.40 after

payment on Sept. 30 of the 27th dividend of 50 cts. per share and extra dividend No. 6 of 50 cts. per share. There was set aside \$173,186.70 for plant and equipment depreciation and \$103,205.40 for ore extinguishment, leaving a net credit to earned surplus for the quarter of \$1,625,348.30 and a balance of \$11,091,045.84 in earned surplus.

PROFIT AND LOSS.

Chino Copper Co., New Mexico.

The report of the Chino Copper Co. for the third quarter of 1916 shows net earnings of \$3,445,291, or at the rate of \$15.84 a share per annum.

Production of copper amounted to 20,606,723 lbs., compared with 18,099,182 in previous quarter.

Costs per pound of net copper produced, after allowing for smelter deductions and crediting all miscellaneous income, was 8.17 cts., as against 8.89 cts. for previous quarter.

The income account compares as follows:

	Sept. 30, 1916.	June 30, 1916.	March 31, 1916.	Dec. 31, 1915.
Net profit from copper	\$3,366,541	\$3,136,278	\$2,667,416	\$2,407,919
Mis. income, rents, etc.	78,750	85,680	79,570	53,797
Total	3,445,291	3,221,959	2,746,986	2,461,716
Dividends paid	1,957,455	1,957,455	1,087,475	869,980
Surplus	1,487,836	1,264,514	1,659,511	1,591,730

Earnings are based on 25.61 cts. per pound for copper, as against 27.49 cts. per pound for previous quarter.

Copper production for past 4 quarters follows:

	Sept. 30, 1916.	June 30, 1916.	March 31, 1916.	Dec. 31, 1915.
First month	6,883,403	4,496,270	5,316,975	6,319,194
Second month	6,326,116	6,359,294	4,617,220	6,339,006
Third month	7,597,204	7,243,618	6,333,255	6,302,045
Total	20,606,723	18,099,182	16,267,450	19,560,245

President MacNeill and Managing Director Jackling say in part:

The total amount of ore treated for the 3 months was 801,500 tons, being an average of 8712 tons per day. This is the highest average tonnage treated by the mill since the beginning of operations, being an average of 47 tons more per day than for the previous quarter. The average copper content of the ore treated this quarter was 1.89%, as against 1.79% for the previous quarter.

The recovery per ton of ore milled for these three months was 25.71 lbs. as against 22.95 lbs. per ton for the previous

quarter. There were produced 62,531 dry tons of concentrates, averaging 16.48% copper, as against 62,241 dry tons of concentrates averaging 14.54% copper for the second quarter of 1916.

In addition to the copper recovered by milling there were 44,038 lbs. recovered from the precipitation plants at the mine, making a total production from all sources for the third quarter of 20,650,761 lbs., equivalent to 6,883,587 lbs. per month.

The ore was of somewhat better concentrating character during this quarter, as well as slightly higher in grade than for the previous quarter; also a further part of the improvements being installed in the mill was put in operation, so that while the wage and material conditions remained practically the same as for the previous quarter, the cost was lower by reason of increased recovery.

During this quarter there was removed by the steam shovels at Santa Rita a total of 1,410,415 cu. yds. of material in place, an average of 470,138 cu. yds. per month as against a total of 1,330,148 cu. yds. for the previous quarter, an average of 443,383 cu. yds. per month. Of the total material removed for this quarter 961,617 cu. yds. were stripping, the remainder being equivalent to 825,914 tons of ore.

The Ray Con. Copper Co., Ariz.

The report of the Ray Con. Copper Co. for the quarter ended Sept. 30 shows net of \$3,299,400, or at the rate of \$8.36 a share per annum.

Production amounted to 19,061,727 lbs. of copper in concentrates, compared with 18,667,664 in previous quarter, an increase of 394,063.

Income account for past 3 quarters compares as follows:

	Sept. 30, 1916.	June 30, 1916.	March 31, 1916.
Net operating profit.....	\$3,280,424	\$3,226,749	\$2,191,592
Miscellaneous income	18,976	15,792	13,954
Total	3,299,400	3,242,542	2,205,547
Bond interest			
Balance	3,299,400	3,242,542	2,205,547
Dividends	1,182,884	788,589	789,302
Surplus	2,116,515	2,453,952	1,416,245

The average net cost per pound of all copper produced for the quarter was 10.348 cts., compared with 10.501 cts. in previous quarter.

Earnings for third quarter this year are based on a price of 27.722 cts. per pound for copper, as compared with 28.067 cts. for second quarter of 1916.

Production for past 4 quarters follows:

	Sept. 30, 1916.	June 30, 1916.	March 31, 1916.	Dec. 31, 1915.
First month	6,606,657	6,162,117	4,164,043	5,894,441
Second month	6,400,636	6,106,657	5,539,408	5,576,083
Third month	6,054,434	6,398,899	6,098,117	5,725,009
Total	19,061,727	18,667,664	15,801,568	17,195,533

The average monthly production in third quarter of 1916 was 6,353,909 lbs., compared with 6,222,555 lbs. in previous quarter.

President Aldrich and Managing Director Jackling in remarks to stockholders say in part:

In addition to copper derived from concentrating ores, there was a total of 620,734 lbs. of copper contained in ores shipped direct to the smelter. This, combined, brings the total gross production for the quarter up to 19,682,461 lbs.

Total amount of ore milled for the quarter was 849,400 dry tons, averaging 1.571% copper, compared with 865,300 dry tons, averaging 1.579% for the previous quarter.

The milling cost for the quarter was 54.99 cts. per ton, compared with 51.41 cts. for the previous quarter.

During the quarter a large part of the improvements which have been in progress for the past year or more, looking to the betterment of metallurgical results, were completed and in consequence the recoveries were the best ever obtained by us. These improvements not only assure better operating results, but also a very considerable increase of copper output.

The average mining and coarse crushing costs of ore milled for the quarter was 83.77 cts. per ton, of which 5.31 cts. was the cost of coarse crushing, leaving the net mining

cost 78.46 cts. per ton, as compared with a net cost of 74.90 cts. for the previous quarter.

The underground development for the quarter was 16,479 ft., making the total development to date 544,423 ft.

Utah Copper.

The Utah Copper Co.'s report for the quarter ended Sept. 30, 1916, shows net profit of \$12,049,460, or at the rate of \$29.66 a share per annum. In the previous quarter net profits were \$9,958,317. Production was 61,079,924 lbs. copper, compared with 48,384,929 in previous quarter.

After making allowances for smelter deductions and crediting miscellaneous income, including Bingham & Garfield railway earnings, average cost per pound was 6.322 cts., compared with 6.726 cts. for previous quarter.

The income account compares as follows:

	Quarters			
	Sept. 30, 1916.	June 30, 1916.	March 31, 1916.	Dec. 31, 1915.
Net profit from operations	\$10,283,878	\$8,675,432	\$6,186,414	\$5,771,281
Other income	90,082	132,509	68,165	240,273
Nev. Con. dividend....	1,000,500	759,375	500,250	500,250
Bingham & Gar. Ry. Div.	675,090	400,000	325,000	407,397
Total net profit	\$12,049,460	\$9,958,316	\$7,079,830	\$6,919,203
Dividends	4,873,470	4,873,470	4,061,225	2,436,735
Surplus	\$7,175,990	\$5,084,846	\$3,018,605	\$4,482,468

Earnings are computed on basis of 25.364 cts. per pound for copper, compared with 26.758 cts. per pound for previous quarter.

Copper production for past 4 quarters follows:

	Sept. 30, 1916.	June 30, 1916.	March 31, 1916.	Dec. 31, 1915.
First month	20,302,228	14,557,282	11,999,910	16,004,607
Second month	20,315,440	15,950,215	11,849,972	13,722,723
Third month	20,462,256	17,877,432	12,714,651	14,497,385
Total	61,079,924	48,384,929	36,564,533	44,224,715

Average monthly production was 20,359,975 lbs. compared with 16,128,309 lbs. in previous quarter.

President MacNeill and Managing Director Jackling say in part:

During the period in question a total of 3,404,300 tons of ore was treated, being 645,800 tons more than the previous high record of the preceding quarter, when 2,758,500 tons were milled. The average grade of the ore was 1.4484% copper, as compared with 1.3810% for the second quarter of the year, and the average extraction was 61.94%. The low extraction was due to the fact that the mills were operated at nearly twice their normal capacity. The average cost per pound of net copper produced during the quarter, after allowing for smelter deductions and crediting miscellaneous income from Utah operations only, including Bingham & Garfield railway earnings, was 6.322 cts., as compared with 6.726 cts. for the second quarter of 1916. This was the most successful quarter in the company's history.

During the period, there was removed a total of 1,585,063 cu. yds. of capping, as compared with 1,659,954 cu. yds. for the second quarter of 1916, being a decrease of 74,531 cu. yds. The average per month was 528,354 cu. yds., as compared with 553,198 cu. yds. for the previous quarter.

The traffic on the Bingham & Garfield railway was greater than for any quarter in the history of that property. An average of 31,746 tons of ore per day was transported from the mines to the mills, and an average of 4026 tons per day of other freight was handled, making a total of 35,772 tons per day, as compared with 27,753 tons per day for the preceding quarter.

Miscellaneous Company Reports.

During September net profits of Goldfield Con. Mines Co. were \$16,072. This compares with \$18,211 in August and \$30,016 in July.

Charles E. Mills, general manager of the Inspiration Con., has been chosen president of Cananea Con., succeeding Dr. L. D. Ricketts, who remains with the company in advisory capacity. Mr. Mills will probably continue as general manager of Inspiration.

Present Huge Demand for Copper Establishes Record Price.

A French inquiry for 225,000,000 lbs. copper for delivery in the second half of next year, the selling of spot electrolytic at a new high record price, a tremendous demand from domestic consumers for first half copper, a serious shortage of copper for this delivery, a pressure on producers to open their books for last half business, have been the developments in the copper market since our last market report. Last week it was stated that there were "rumors that another tremendous foreign purchase is impending." The French inquiry was announced on Thursday. It was stated that "domestic consumers are willing to place their second half requirements under contract." Definite acknowledgement of such inquiries has since been made by leading producers.

Business in copper since our last report has been excited. Consumers who were in need of first quarter copper shopped around all of the leading producers without filling their wants. Dealers who are holding large blocks of metal available for nearby delivery are selling sparingly waiting for higher prices. Copper has sold at 32¼ cts. for spot 31 to 31½ cts. for first quarter delivery and 30 to 30½ cts. for second quarter delivery. Predictions that the red metal will sell at 40 cts. a pound before the end of the year are being heard. The extent of the copper requirements of domestic consumers for delivery in the first quarter that must still be purchased appears to have been greatly underestimated. One important wire drawer is now seeking 6,000,000 lbs. a month for the first quarter. Several brass makers are negotiating for 2,000,000 to 3,000,000 lbs. a month for that delivery. There are even some million pound lots being sought for December delivery. The amount of copper inquired for in carload lots is also tremendous.

With dealers controlling the entire situation over the first quarter the fact that a premium market for copper has arrived cannot be disputed. The inability to increase production of copper is primarily the cause of the tight situation now prevailing. Consumers who felt secure in the belief that output would run above 200,000,000 lbs. a month by the first of the new year have since come to a realization of the fact that consumption will be greatly in excess of the output. Producers warned these consumers of their peril, but they failed to heed the injunction. Price considerations are no longer the determining factor as to whether a consumer will buy copper.

Melters who are protected over the first half are clamoring for coverage over the second half. There has been a remarkable change of sentiment among copper consumers. The opinion is now more general that the future of copper does not depend wholly on the continuance of the war. With Europe buying copper a year ahead on orders that cannot be cancelled and willing to pay the prevailing high prices,

domestic consumers have found that the fears of a reaction, if the war should end, are baseless.

Producers are today limiting even transactions for the second half of next year, to regular customers. Buyers who have made a practice of shopping around, are finding that their "penny saved is a penny earned" policy is of no earthly advantage to them when the market turns from a buyers' to a producers' market. It has come down to apportioning production. Output cannot be increased sufficiently to take care of the greatly enlarged world demand. Facilities may be created, but labor cannot and there is the rub. Plants cannot be run forever without repairs and when parts for repairs cannot be obtained plants are closed. Thus notwithstanding the desires of producers to bring the output up to 225,000,000 lbs. a month there are factors that prevent them from so doing.

Cleanliness and Attention to Details Necessary in Chemical Work.

Neglect of cleanliness and attention to details by chemists and assayers in making chemical analyses means inaccurate work, and analytical work that is not accurate within certain well-defined limits is worthless or even worse. The importance of these matters should be thoroughly inculcated in schools where chemistry and assaying are taught. They usually are emphasized but the words of the professor are not always heeded, some men by nature being careless and sloppy workers. Such men were not intended to be chemists.

There is a great difference between sanitary cleanliness and chemical cleanliness. Glass measuring apparatus must be free from all greasy matter, if accurate measurements are to be made with them. A burette that is greasy in the slightest degree will retain drops of the standard solution with which a titration is being made, causing high readings. Cleanliness about delicate balances is essential. Fumes and dust should be kept away or the accuracy of the balance is almost sure to be impaired. Dusty and corroded balances are all too common sights. Balances must be protected from the direct rays of the sun as the uneven expansion produced makes them very erratic.

Many precautions for manipulation might be mentioned, but it is our purpose merely to call attention to the importance of developing a habit of cleanliness and attention to details that are so essential to accuracy and rapidity in performing chemical operations.

Utilization of Wastes.

One of the important questions that has occupied the attention of past meetings of the American Mining Congress and was considered in its various aspects at

the meeting held in this city this week is the utilization of wastes.

Practically everything has a commercial value. Wastes are only waiting for some genius to discover a use for them. The term "waste product" has given way to "by-product." Some of the great problems of modern technology are concerned with the means of extracting profits from these so-called waste products, or at least with the finding of an outlet for them by which they can be disposed of without becoming a source of annoyance or expense.

Of the material hoisted from mines only a small proportion of it—the metallic contents—is sought primarily, the remainder going to the waste or tailings dump at the mines or to the slag dumps at the smelter. Both tailings and slags are no longer considered useless wastes, important uses having been found for them in recent years. Slag is now used for making roofing, cement and other products. Tailings have found an outlet as an almost ideal material for railroad ballast and road making, and as an ingredient in cement concrete for building construction.

The use of mine and mill tailings for these purposes has become of considerable economic importance, especially as a ballast in railroad and wagon road building, in which they are highly prized.

It is gratifying to owners and operators of mines whose ores carry values in silver to note the stiffening price of silver—a 13-ct. raise since the low of July. This increase means much to mines of large tonnage, where silver is of any moment as a by-product, as the copper and lead mines of the country. With the unusually high prices for some supplies any increase on the returns for silver is a welcome addition to the revenue of the operators. Mines in those regions where silver is still the chief content of the ores, as regards values, will be benefited most materially by a continuance of the upward tendency of silver, however small each step in the ascendancy may be. The outlook for the balance of the year, at least, is encouraging.

The American Mining Congress closed a very successful session in Chicago—the nineteenth annual—on Thursday evening of this week. The attendance was unusually large—coal mining men, however, predominating, with the various sessions of that branch productive of a number of excellent papers. The attendance of the metal-mining fraternity was disappointing, but those who were here were treated to some highly instructive papers. A complete account of the meetings will be given in Mining and Engineering World in next week's issue.

Some idea of the immensity of the expenditures for labor by American mines and works may be gained from the October payroll in the Butte camp. Out of a total for all mines in the camp of approximately \$2,500,000, Anaconda alone paid \$1,672,265.

PERSONAL.

Walter Fitch of the Chief Cons. Co. is at Houghton, Mich., for a brief visit.

P. H. Crawford has accepted the superintendency of the Grecia mine, Nicaragua.

William Motherwell, flotation engineer, has left Nelson, B. C., and will go to Baker, Ore.

J. W. McBride, Spokane, Wash., has returned from inspecting properties in Troy, Mont.

J. Cleveland Haas, mining engineer, Spokane, Wash., has returned from a trip to Princeton, B. C.

H. L. Christensen now has charge of all mill work being done at the Alaska Juneau property, Juneau, Alaska.

W. E. Mitchell now has charge of the Anaconda Copper Co.'s plant for the treating of residue at Great Falls, Mont.

Charles McKinnis, secretary of the Caledonia Mining Co., who has recently been in Alaska, has returned to Kellogg, Idaho.

Leo F. Arnold, mining engineer, has returned to Chicago from a trip during which he inspected properties in Arizona and Oregon.

C. T. Griswold of the Associated Geological Engineers is in Wyoming. Ernest Marquardt of the same organization is in Kansas.

William Nicol, formerly a professor at the Queen's School of Mines, Kingston, Ont., has resigned and gone to Los Angeles, Calif.

C. E. Mills, general manager of the Miami Copper Co., Miami, Ariz., has returned from a trip to Santa Barbara and Los Angeles, Calif.

A. G. Larson, mining engineer, Spokane, Wash., has been in Nelson, B. C., and will go from there to Boundary, Wash., on professional work.

F. A. Knapp, secretary and manager of the Portoma Co., Wallace, Idaho, has returned to Portland, Ore., from a trip of inspection to the properties.

E. L. Hayes, who is on the efficiency force of the Calumet & Hecla Co. at the Isle Royale mine, has joined the selling force of the Ingersoll-Rand Co.

Arthur K. Adams, mining geologist for the Mascot Copper Co., Dos Cabezas, Ariz., has accepted a similar position with the Andes Copper Co., Chile.

Fred Ely, field engineer for Gunn-Thompson & Co., Superior, Ariz., has recently been in New York and left for an indefinite stay at Vancouver, B. C.

Wong Kwong, chief engineer for the Yangste Engineering Co., Hankow, China, has been in Salt Lake City and left for various cities on the Pacific coast.

Ernest LeDuc, president of the Big Ledge Co., Prescott, Ariz., has returned to Duluth, Minn., from a trip of inspection to the company's properties.

Eustice Dwyer, mining engineer with the American Smelting & Refining Co., Superior, Mont., has been transferred to the company's Salt Lake offices.

H. W. Du Bois, consulting engineer for the Alaska Copper Corporation, has returned from the Copper River country, Alaska, to his headquarters at Philadelphia, Pa.

Pres. F. W. McNair of the Michigan College of Mines and Herman W. Fesing of Houghton, Mich., attended the annual meeting of the American Mining Congress at Chicago this week.

John R. Stanton of New York, president of the Mohawk and Wolverine companies, with Fred Smith and Angus Smith of Detroit, directors of the White Pine Extension, and Mr. Van Law of Boston arrived at Houghton, Mich., the 14th

to inspect the mines of the district and some of the properties near the White Pine Extension on the Nonesuch or White Pine formations.

Chas. Chynoweth of Houghton, Mich., secretary of the Wolverine & Arizona Co., will attend the annual meeting of the company at Bisbee, Ariz., and will also visit Prescott and Jerome.

C. G. Sheldon has become a member of the engineering staff of the Munroe mine at Iron River, Mich., succeeding K. G. May, who has gone to the smelter of the Anaconda Co. at Great Falls, Mont.

Capt. Jos. Chenoweth of Calumet, Mich., has gone to St. Augustine, Fla., for the winter. Capt. Chynoweth was formerly superintendent of the Allouez, Old Colony, Mayflower, Contact, and Continental mines.

SCHOOLS AND SOCIETIES.

College of Mines and Engineering at the University of Arizona.—A short course for miners is announced. Tuition is free to residents of the state, others pay \$1 per course. Prospectors have 5 weeks, starting on Oct. 30, field geology 2 weeks from Dec. 4, assaying 10 days from Jan. 3, metallurgists 3 weeks from Jan. 15, flotation 1 week from Feb. 5, and miners 6 weeks from Feb. 12.

NEW PUBLICATIONS.

Magnetic Properties of Cobalt and Iron-Cobalt Alloys. By Herbert T. Kalmus and K. B. Blake. Canada Dept. of Mines, Mines Branch, Ottawa, Ont. Report 413; pp. 18; illustrated.

This research work was carried on at Queens University for the purpose of finding more commercial uses for cobalt. The apparatus and nature of the experimental work is described and followed by results and discussion of the same with some of the findings plotted in a curve.

Rescue and Recovery Operations in Mines after Fires and Explosions. By James W. Paul and H. M. Wolflin. Washington, D. C., U. S. Bureau of Mines. Booklet; pp. 109.

As might be mistaken from the title, there is no information in the contents regarding first-aid work. The contents is confined to bringing out the proper way to manage things immediately after the accident has happened and what to do to prevent accidents. Who to call and how to direct the crew coping with the affair are among things considered. For example, it is stated a fresh hoisting engineer should relieve the one who was at work when the accident happened since his system is rendered unfit by the shock.

The Flotation Process. By H. J. Stander. Mining World Co., Chicago. Book; pp. 175; illustrated; \$3.

The flotation process is so comparatively new that previous texts have been unable to treat on the subject in logical sequence. To date most people interested in flotation are merely students with respect to the process and the author has made this book of greatest value to the student, not only in the college but also those practicing in the field. It has been gotten up in a concise yet complete manner. The theory of various phenomena are described so as to be of value in studying out flotation problems in practice and, to make the description more vivid, descriptions and reference are made to operating plants. Under Flotation Processes brief descriptions are given of the principles of the several kinds of flotation. Various flotation machines are then described and a very complete chapter follows on the details of methods of testing and in some cases results which have been obtained by the author and others. There are separate chapters on Surface Tension and Occluded Gases, The Electrical Theory of Flotation, Interfacial Tension and Colloids, and the Function of Oil and Acid in Flotation. There is also a

brief chapter on costs with information on litigation, patents and a complete bibliography of flotation literature to date.

Concentrating Ores by Flotation. By Theodore J. Hoover. The Mining Magazine, London, E. C. Book; pp. 320; illustrated. For sale by Mining World Co., \$3.75.

In this, the third edition of a book which needs but little introduction in the way of description, the principal addition is that of Chapter XIII, which reviews the progress made in the art of flotation from 1914 to 1916, during which time considerable development in the industry has been witnessed. New findings made during this period are described in the chapter. There is a list of patents obtained during the period and a bibliography of current literature published during the same time.

Report on Mining Operations in the Province of Quebec During 1915. Quebec, Department of Colonization, Mines and Fisheries, Mines Branch. Report; pp. 146; illustrated.

The more important of Quebec's products are asbestos, zinc and lead. Brief separate reviews are made of the several minerals produced in the province and a list of the operators is given and classified according to the mineral they produce. A review of accidents which occurred during the year is given. The last 44 pages are confined to a report on the geology of the zinc-lead deposits in Montauban and Chavigny townships of Grondines.

Geology of the Hound Creek District of the Great Falls Coal Field, Cascade County, Montana. By V. H. Barnett. Washington, D. C., U. S. Geological Survey. Bulletin 641-H; pp 17; illustrated.

The contents of the bulletin is of a purely geologic nature regarding the structure of the formation and coal seams which do exist but to date have not been opened to an extent which will permit of saying whether or not they are of commercial value. The bulletin will be found of value as regards literature on the possibilities of coal in the area since the principal reason for the study of this area was to classify the land as mineral land or otherwise.

A Reconnaissance for Phosphate in the Salt River Range, Wyoming. By G. R. Mansfield. Washington, D. C., U. S. Geological Survey. Bulletin 620-O; pp. 19; illustrated.

This investigation was made because of certain lands which had been withdrawn from mineral rights. The area lies on the west flank of the Salt River range. The data obtained it is stated in the bulletin showed that the phosphate deposits which occur in this area are inferior to those of Idaho though there is a medium grade which occurs that may be held as a good reserve. In view of the higher grade deposits in Idaho and low prevailing prices it is probable that the deposits will not be worked for some time.

TRADE PUBLICATIONS.

Recording Pressure and Vacuum Gauges. The Bristol Co., Waterbury, Conn. Catalog No. 1001; pp 63; illustrated.

Illustrations and description of each class of recorder of this type are given. Reproductions of some charts from practice are shown and a very complete list of charts of different kinds to be used on the gauges is included.

Boiler Tube Cleaners. Lagonda Mfg. Co., Springfield, O. Booklet T2; pp 15; illustrated.

With illustrations and brief descriptions a line of boiler-tube cleaners operated by air, steam or water are shown. Included in the pamphlet besides these are automatic valves, oil strainers, filters, etc., reseating machines, boiler tube cutters, and feeding devices for cleaners in connection with Stirling boilers.

Drill Sharpener. Ingersoll-Rand Co., New York. Bulletin Form No. 4122; pp 24; illustrated.

The sharpener in general is of the usual type of shar-

pener which is pneumatically operated. The first few pages of the bulletin described what may be expected from the sharpener as regards capacity and variety of the work to be done. With views, drawings and description the construction of the machine is gone over. The concluding pages are confined to reviewing good practice in the proper use and making of rock-drill bits.

Automatic Weighing of Coal and Water in Power Plants. Richardson Scale Co., Passaic, N. J. Bulletin 101; pp 63; illustrated.

The first pages consist of a general discussion of power plant practice and efficiency. Complete descriptions of construction and operation of the company's equipment are then given and views shown of installations of the equipment at various plants. Drawings are shown of the general arrangement of plants and equipment where coal and water for the boilers is weighed. This is supplemented with discussion and further information regarding the design.

Spraco Paint Gun. Spray Engineering Co., Boston, Mass. Booklet; pp 12; illustrated.

The gun and its operation are described. In the first few pages of the booklet it is stated that the paint gun is a practical hand tool for applying any liquid coating. The equipment consists of the gun, hose connection and a portable, air-tight tank in which the liquid is contained and into which pressure can be applied to force the liquid out through the gun. In various work in shafts and stations underground this tool will be found of advantage as well as in applying paint and coatings to buildings about the mines and plants such as mill and smelter connected therewith.

Soot Cleaners. Vulcan Soot Cleaner Co., Du Bois, Pa. Bulletin; pp 91; illustrated.

In the first three sections of this bulletin the question of soot, its formation and the advantages to be had by cleaning it away, is discussed and reviewed in a practical manner to show why soot cleaners should be in every power plant. Section IV takes up Vulcan cleaners as applied to water tube boilers of different classes and for each type a drawing is reproduced showing a Vulcan cleaner installed though where similar types occur they are referred to each other to save space. Section V is similar to Section IV but confined to fire tube boilers and Section VI to economizers.

Flotation Oils. General Naval Stores Co., New York. Catalog; pp. 12.

Oils are separately described with respect to the way in which they are manufactured and the uses for which they are best adaptable in flotation work, that is as a frothing or collecting oil. Each standard oil handled by the company is then considered separately. Under each heading are the subheads: kind; method of manufacture; color; specific gravity limits; flotation value; nature of froth; and use. The company states that the catalog has been gotten up with respect to the mill man rather than the experienced metallurgist and under the last subhead "Use" suggestions will be found for combining the oils so as to obtain an oil with the proper physical properties to successfully treat any ore.

INDUSTRIAL AND TRADE NOTES.

Aerial tramways recently supplied by A. Leschen & Sons Rope Co. of St. Louis were as follows: Queen of the West Mines Co., Cornucopia, Oregon, a gravity 2-bucket tram 3200 ft. long, the line having a fall in this distance of 1456 ft. This tramway will have a capacity of 6 tons of ore per hour, and replaces a single-line tram of another manufacture. Cottonwood Coal Co., Lehigh, Mont., a 2-bucket tram for the disposal of waste. This line has length of 800 ft., and carries at the rate of 20 tons per hour. The tram has 1 3/8-in. diameter special-steel track-ropes, and a 5/8-in. diameter traction-rope. The carriers are of 21-cu. ft. capacity. The material is dumped by means of an aerial trip at any point along the line.

Late News From the World's Mining Camps

Editorial and Special Correspondence.

ALASKA.

Whitehorse.

Conditions and progress here are considerably above what they were last year. The Pueblo is rushing ahead, and a new boiler is being installed. The old sheds are being torn down and new ones erected. Work is also being rushed at the War Eagle. This mine is handicapped only by poor transportation in getting their output to the railroad.

Skagway.

W. L. Stevenson of this city has purchased property in the Kantishua district from W. R. Taylor. The price paid was \$45,000 cash.

Sitka.

Activities on Windy Arm are manifested in the recent shipment of 1200 sacks of ore from the Venus mine to the Granby smelter. Supt. McFarland is making preparations to commence work at the Montana and a force is at work taking the ice and water out of the mine. Both of the mines are being developed by the Harper interests. The M. & M. mine has produced ore valued at \$165. McFarland expects his first shipment from the M. & M. on Polley Gulch. Three men are breaking and sacking high-grade silver. Work will be pushed through the winter at practically all of the mines now open by McFarland.

Juneau.

At the Goldstein group located on the Salmon creek side of Mt. Juneau a 48-ft. prospect tunnel has been driven to cut the vein and good showings of free gold in the quartz have already been made.

Knik.

All lands included within Alaska Townsite Withdrawal No. 4, in sections 22, 23, 26 and 27, T. 17 N., R. 1 W., Seward Meridian, have been restored. This land was withdrawn when it was thought it would be needed for railroad and townsite purposes. It is found that there is no need for the land. It is located in the Matanuska Valley, about ½ mile from the main line of the railroad and within 2 miles of the new town of Wassilla on the Knik-Willow Creek wagon road.

Fairbanks.

It is rumored that Morrison & Johnson, drifting on No. 6 below Cleary, struck pay on the claim on which W. C. Gates made a fortune. They have struck 6 ft. of gravel that will run in the neighborhood of \$5 per sq. ft. of bed rock.

Kennicott.

Charles McKinnis, Wallace, Idaho, on returning recently from Alaska, states that in the Jumbo an ore shoot is being mined which is 40 ft. wide and 125 ft. long. Prospecting is being done in this part in an area about 200 miles wide. During the summer a strike was made in the Mother Lode Co.'s ground adjoining the Bonanza mine. The company is said to have 500 tons of good ore ready for shipment, and other ore opened to keep shipments going at the rate of 250 tons per month all winter. It has a large tonnage of milling ore on the dump and in the mine, and will build a concentrator next summer.

Engineers' estimates show about 600 tons of 40 to 50% ore on the Josevig-Kennicott claims which are amongst the most recent developments.

The newest development in that immediate district is of the Josevig-Kennicott claims. These were bonded to Seattle and Spokane parties last fall. In the incorporation of the company, D. K. McDonald, of Spokane, was made president, and M. E. Hay, former governor of Washington, vice-

president. The other members of the directorate are bankers and lawyers of Seattle. Wallace people own some stock in the company.

The company is now building a road from the Bonanza mine to the property. The road extends 6 miles across the Kennicott glacier, and 3 miles on the mountain-side from the end of the glacier to the workings. The company is shipping in supplies from Seattle, via Cordova. A large crew will be put to work next spring.

The company has already shipped out 3 tons of ore from various open cuts on the vein which, it is estimated, will run from 40 to 45% copper.

ARIZONA.

Globe.

With the mining of high-grade sulphide on the 13th and 14th level, reserves have been added to at the Arizona Commercial by the opening of high-grade in a crosscut on the 10th level. It is not, however, quite as good as that on the 13th and 14th levels. On the 14th level the smelting ore is averaging 7% and concentrating ore 4%. The body shows variations from a few feet to over 40 ft., the average being about 20 ft.

Miami.

Work on structures for the reclaiming of water from the Inspiration mill is progressing. Instead of pumping the whole water supply from the wells and performing this against a high head, the bulk of the pumping is done at the top of the dam which is at a considerably higher elevation than the wells. The second tier of trestle work for the launders has been built along the face of the tailing storage dam north of the smelter. This dam is at the lowest elevation of any of the three dams which are strung out in a row along the canyon. Its face at present approximates 50 ft. in height.

Chloride.

The power line has reached camp and the town will be electrically lighted and the mining machinery be electrically driven just as soon as the transformer station is completed and the line extended throughout the camp.

Activity among the mines continues to increase and good strikes are of daily occurrence. The strike of 4 ft. of high-grade ore in the shaft at the Georgia was good news; the widening of the strike at the 175 level in the Schenectady, the finding of a rich shoot in an old winze that had just been cleaned out on the Silver Hill, together with 73 sacks of high-grade that had been filled in years past from the same shoot and abandoned for reasons that will perhaps never be known; the find of high-grade on the Rattlesnake group just south of Silver Hill, kept the public interested throughout the week.

Another feature of importance was the taking over of the Elkhart by W. L. Leland and San Francisco capitalists, and the announcement that a new shaft will be sunk immediately to 1000 level. Also that the old mill will be remodeled and modern concentration processes installed.

The raise from the 1400 to the 1170 at the Tennessee is within 50 ft. of breaking through. This raise will provide air for the lower workings and enable a larger force of men to work below.

The Cerbat mine has begun shipments to Selby. R. W. Richardson just made a shipment of concentrates. A. W. Clapp shipped concentrates last week. Gus Theida and Alois Herbst are stopping and will start the old Gem mill in a

few days. A new hoisting engine was installed on the Copper Age and another engine is on the way for use at another point on the same property.

The tunnel at the Hidden Treasure is within 150 ft. of its goal and is going forward at the rate of better than 4 ft. daily.

A representative of the Callow Engineering Co. of Salt Lake is here, making an examination of Hidden Treasure at the request of the Hidden Treasure Co. The company will submit plans for a 150-ton reduction plant.

Leasers are becoming active and applications for blocks of ground being made. This results from presence on ground of four milling companies who are striving to get custom mills erected. The Silver Hill will begin work on its mill at once. The Steffy mill will also begin work at once. Sufficient ore contracts have been made to provide 250 tons daily. The Copper Age mill will add a custom department. This has encouraged leasers, as it will insure them home treatment of their ores and hence a profit.

Jerome.

Decatur Copper Co. with main office at Decatur, Ill., has just been reorganized with the same number of shares, 2,000,000, which will be exchanged at the rate of two of the old for one of the new, thus disposing of 850,000 shares and leaving in the treasury 1,150,000 shares of which 400,000 shares will be offered for sale and 750,000 in the treasury. The new board of directors are: Philip Carroll, Hancock, Mich.; F. P. Wells, Chicago; C. M. Hearst, W. J. Wayne, W. C. Fields, and S. T. Lowry, Decatur. The property lies, it is thought, in the way of the great vein of the United Verde Extension and next to the Green Monster.

Quartzite.

Lidgerwood Mfg. Co., through the Los Angeles office, has sold a 1½-yd. excavator to the Yuma Con., to handle dry placer material on the latter's gold property near Quartzite. The excavator will be operated by electric power, taking up material from the surface and dumping it into a hopper from which it is loaded into 4-yd. ore cars and hauled by electric locomotives to the mill. The dry milling plant is being equipped with a Quenner chain-hammer pulverizer and Stebbins dry concentrating tables, and a belt conveyor for stocking the tailings. Concentrates made from this dry placer dirt, after taking out the coarse gold, ran \$180 gold, 22 ozs. silver and 40% lead. Excavations made through the false bedrock disclosed a good grade of placer material below it.

Oatman.

The Iowa is now entering the foot wall of its vein at 400-ft. depth, and from the mineralization of the wall rock, and signs of replacement of calcite by quartz, the operators believe that they will encounter a pay shoot not far from where the crosscut taps the vein.

Picture Rock, Arizona Tom Reed, Carter, Boundary Cone, Gold Road Bonanza, San Francisco, Mohawk Central and Crescent are other properties which should soon be due for interesting developments.

In the Tunner level of the Times, which has resumed operations, a full face of ore averaging better than \$20 has been encountered, and a drift is now into this ore about 20 ft.

Taken as a whole, Oatman today looks better than ever. A number of insufficiently financed concerns have suspended, but those now operating are performing their work with an earnestness and determination which promises much for the future of the camp, and several other concerns which have just been re-financed with strong capital back of them are making preparations to resume early.

The Gold Dust is steadily developing ore on two levels, and will soon have the old Orion mill equipped to handle 25 tons of its ore daily. The Zimmer centrifugal amalgamation process will be used. Laboratory tests have shown a high saving on these ores, the gold in which is so fine that it cannot be caught by ordinary amalgamation processes.

The Oatman United, at a depth of about 150 ft., has passed through what it believes to be the first fold of a big vein which its operators believe may be the Big Jim vein,

and now is entering the hanging wall of what seems to be the reverse fold of this same vein. J. K. Turner, of the Goldfield Great Bend and Jumbo Extension, is consulting engineer for the Oatman United.

The Big Jim shows the finest example of a folded vein which it is possible to find. On the 485 and the 400 levels, the strike of the vein is N 60° E, and its upward strike is toward the south, at an angle of about 85°—almost perpendicular. At about 200 to 240 ft. depth, the vein encounters a massive dike, the strike of which is parallel with that of the vein, runs upward along the wall of this dike for some 40 ft., and then turns back to the north at an angle of about 56°. This elbow, at point of present work, is near the southerly side-line of the Big Jim, and indications are that further to the east, this elbow will be thrust out some distance beyond its southern side-line, but that the upward inclination of the vein at that point brings its apex back to fully 120 ft. within the Big Jim lines. It is one of the most interesting and geological studies of vein folding.

CALIFORNIA.

Zabriskie.

Fifty Associates Securities Co., Los Angeles, is developing large bodies of talc in San Bernardino and Inyo counties, near the line of the Tonopah & Tidewater railroad. After stripping off the overburden, the talc deposit is hored into with coal augers and blasted with black powder. An analysis of this material shows the following content: SiO₂, 59.3%; MgO, 27.14%; CaO, 2.52%; Al₂O₃, 0.43%; FeO, none; H₂O, 5.38%. This is deemed exceptionally high grade, and commands a market among manufacturers of paper, surgical and toilet powders, automobile tires, lubricants, cotton bleaching and paints. It is also used in tanneries, in ceramic arts and in rubber factories. F. W. Remy, E. M., is directing this work.

Caliente.

The Big Fifty antimony mine, 15 miles from Caliente, Kern county, has been developed by adit levels, exposing a 50-ft. ore body, carrying 30% stibnite in a porphyretic gauge. The ore occurs within a porphyry dike which extends along a contact of limestone and granite, the vein having a dip of about 80°. Shipments amount to 4 or 5 tons per day of the ore of higher grade. A much larger tonnage of lower grade ore is available, and for this a mill may be built. The property belongs to the Fifty Associates Securities Co., Los Angeles, for which F. W. Remy is mining engineer and geologist.

Goldstone.

An important strike was made on the Gold Ring claim of the United Goldstone group last week. The vein is 4 ft. wide and has been opened for 70 ft. with strength displayed as developments advance. About 22 ins. of the center of the ledge carries high values, with 3 to 4 ins. picture ore. It is stated the ledge averages throughout its total width \$72 per ton.

Preparations are being made for resumption of work on the Big Drum group. Large quantities of medium-grade ore are exposed, and shipments to the custom mill are contemplated. The management contemplates erecting its own mill as soon as a satisfactory reduction process has been perfected. The company is controlled by the Shorey-Brown interests of Boston.

The Daggett custom mill is being improved and will soon be in shape to treat 200 tons daily. Some trouble has been experienced in securing a satisfactory extraction, but no further difficulty is anticipated. Boston capitalists control the plant and are supervising it.

Victorville.

A deposit of high-grade tungsten has been discovered on the property of the United Tungsten Mines Co., in the Morongo district. The ore is high-grade scheelite, occurring in a formation of granite and limestone. Contracts have been awarded for supplies, machinery and building material, and construction of a 50-ton plant will be rushed. William

K. Weaver, Warren Gillelen, J. Wells Smith, H. A. Cole, Frank F. Peard, E. M. Coplen and other New Yorkers are interested. D. G. Kidder is manager.

Mt. Gaines.

A large interest has been acquired in the Mt. Gaines Mining Co. by Pennsylvania people, headed by Joseph Cauffel, ex-Mayor of Johnstown, Pa. George Kislingbury has been chosen general manager and consulting engineer, and arrangements made for extensive operations. The Mt. Gaines mine has produced upward of \$1,500,000 in gold, but has been idle since 1911. It is to be immediately unwatered and vigorous work prosecuted. Considerable California capital is also interested. The Mt. Gaines is said to have been the first gold mine in the State to be operated by electric power.

Keeler.

The deposit of rich silver-lead ore lately opened in the Cerro Gordo continues to develop splendidly. As depth is gained the vein appears to be gaining strength with the values maintaining their original average. In the lower workings high-grade zinc is mined and heavy shipments made. The tramway is taxed to capacity to handle the tonnage.

Jackson.

The strike of the miners in Amador county came to an end last Friday, following instructions from the executive offices of the Western Federation of Miners. In these instructions it was stated the strike was ill-timed, without merit, and had been called without instructions from the head officials. All the mines are resuming with full crews as rapidly as places can be found for the men, and roads and trails are crowded with returning workers. With the exception of a few particularly objectionable leaders, all the men are being employed in their old places.

Nevada City.

The North Star Mines Co. is preparing to construct an aerial tramway from the Champion mill to the Providence shaft, which will shortly become the main outlet of the Champion group. Connections of the Champion and Providence mines at a depth of 1800 ft. are proceeding. On the 2700 workings of the Champion a 4-ft. ledge of milling ore has been encountered and is apparently developing into an orebody of importance. Thirty stamps are dropping at the mill, and ten more will be placed in commission in the near future. One hundred and fifty men are employed.

Unwatering of the Delhi mine, on Columbia hill, has been completed and active exploration is about to start. According to miners ore of excellent grade was exposed in the shaft when water forced closing of the property, and if this is proven by actual work, the mill will be placed in commission at once. Considerable low-grade quartz is exposed in the upper levels.

The Sailor Flat hydraulic mine has been taken over by local people and will be worked by the drift method. New lines of flumes have been laid and a good water supply developed. Large bodies of excellent gravel have been blocked out. The outlook is considered encouraging for a profitable season.

Hammonton.

The Yuba Gold Fields Con. will launch dredge No. 16 on No. 20. It will be of steel throughout, equipped with 16-cu. ft. buckets, and designed to handle over 450,000 cu. yds. of material per month. It will closely resemble No. 15 dredge of the Yuba fleet, but will be equipped with improved gold-saving devices and is expected to be even more efficient in every department.

Placerville.

The Placerville Gold Mining Co. has sold 23 claims to a syndicate of California and Eastern people headed by J. W. Northrop, San Francisco. The deal includes the Pacific mine, which has been opened to a depth of 2000 ft. by shaft and winze and five properties located within the city limits of Placerville. For 40 years the Pacific was a consistent producer, but at the outbreak of the European struggle was closed by its English owners. Under the new ownership the Pacific shaft will be dewatered and drifts thrown out to intercept promising shoots disclosed in adjacent territory. R. Chester Turner, general manager of the Brunswick, Con.,

at Grass Valley, has been chosen consulting engineer and general manager.

The Ohio gravel mine, near Smith's Flat, has been sold to J. A. Forsythe and associates of Alaska by William Richards and W. F. Fairchild. Work is to start immediately and some equipment will probably be installed. The Ohio formerly yielded substantial dividends, but has lain idle several years.

Tuolumne.

A marked mining revival is reported throughout the east section of Tuolumne county, and considerable Eastern capital is being invested. In the Columbus a strong vein of \$10 ore has been encountered in the shaft, which is being deepened to 500 ft. In the nearby Carlotta rich ore is showing and the management is preparing for more comprehensive work. Operations have been resumed at the North Star, formerly a good producer.

The Confidence Mines Co., a strongly-financed \$1,000,000 corporation, is rapidly completing arrangements for extensive work at this property. Considerable new equipment has been decided on, and some orders placed. The Sonore & Duffield property has been reopened. The United Mines Co. is clearing the legal title to its holdings and expects to start along broad lines in the near future. Options have been taken on the Chapparel and Garfield, and other old time producers are receiving attention.

Grass Valley.

The Indiana Dredging Co. has taken a bond on several miles of land along Greenhorn creek and is exploring the territory with prospect shafts. Because of the heavy water flow encountered at shallow depth steel caissons are sunk and the shafts kept clear with a centrifugal pump. Satisfactory results will be followed by construction of a large dredger. The company is one of the leading dredging enterprises in California.

On nearby ground Louis Girdetz and associates are mining rich gravel with a drag-line scraper. The holdings comprise part of Arkansas canyon, and extend for 3 miles to the You Bet placers. Much gold has been recovered by surface placering, but the bedrock has never been worked.

Howland Flat.

Several mines have been reopened and preparations for resumption of hydraulic operations are proceeding actively. The huge restraining dam across Slate creek is nearing completion and as soon as it is accepted by the California Debris Commission, hydraulic operations will start at Howland Flat, Port Wine, St. Louis, La Porte and other camps. Considerable work is going on at the Miners' Home, Wink-eye, and other mines.

Happy Camp.

At the Gray Eagle mine, recently acquired by the Mason Mines Co., the camp is being enlarged and the mine placed in condition for operations on a large scale. The working force has been increased and development of new ground is proceeding. Facilities are also being provided for storage of ore. It is rumored the company plans the building of a concentrator at the mine in the spring, and that concentrates and the higher-grade ores will be shipped to the smelter at Thompson, Nev.

Hart.

Oro Belle Mines Co., whose main office is at Houghton, Mich., will resume mining under the management of the John Hays Hammond-Royer interests about Dec. 1. The new company was organized Oct. 26 and the old company will hold a meeting of the stockholders Dec. 12 to dissolve and distribute the new company's stock on the basis of one share for two of its own; the books closed the 9th and will be opened Dec. 13. The Woodward vein is believed to have a large quantity of low grade gold ore which will prove to be profitable.

Atolia.

The Atolia Mining Co. has temporarily suspended operations, pending shaft improvements which will consume about 60 days. Lessees left portions of the property in bad condition and repairs were necessary. Most of the miners have gone to other camps, but a small amount of tungsten is still being produced by independent operators.

COLORADO.

Ophir.

Drifting for the ore bodies of the Matterhorn Mining & Milling Co. is now being done through the Butterfly.

Wichmann & Co. has shipped 1 car from Santa Cruz and Otho Bever and Lou Lomax made a small shipment from the Pike County lode. The Highland Mary is driving a tunnel and Newton Sankey and Jim Belisle have been doing development on a gold property.

The Black Bear mine is enlarging its 450-ft. shaft and will install an electric hoist. Supt. Nevala intends later to sink the shaft further as better ore is noted in the deeper workings.

Rico.

Dead work done to develop ground has retarded production at the Rico-Wellington considerably during the past few months. This work is now nearly completed and uninterrupted production will commence soon and continue through the winter.

Telluride.

The trapway on the Carruthers lease between the mine and new mill is finished and will be started immediately. There is plenty of ore on the mine dumps to keep it busy all winter with what is gotten out regularly.

The Liberty Bell Mining Co. has just about closed a deal for the purchase of ground on their east end lines from the Smuggler-Union Co.

October shipments were: Tomboy 61 cars of concentrates; Smuggler 51; Liberty Bell 15; Black Bear 1; total 128 cars.

Leadville.

Since dewatering the Down Town Basin, the first shipments have been made from the Penrose shaft. Two cars of high grade iron-manganese were sent to the A. S. & R. Co., Denver. A steady tonnage will be extracted and the output increased gradually for some time. The body is just being opened and has only a comparatively small breast for stoping. As the ore is developed, a larger force of men will be put to work. A decrease of 300 gals. per minute has been noted in the flow since the reaching of the bottom level.

The bottom of the Hilschle shaft has been reached after several weeks of work. It was held up by a heavy cave in the shaft which necessitated considerable retimbering. Work is now under way cleaning out the drift from the Hilschle to the Newell shaft. It proposed to carry on some development through the Newell. Owing to the displacement from the Pendery fault, the formation in the Newell is found much deeper than in the Hilschle. Here large bodies were found directly under the wash at the contact of the lower quartzite and the white limestone. The Newell shaft did not penetrate through the white porphyry to the first contact between this and the blue lime formation which is most favorable for ore deposition.

Colorado Springs.

In a recent report of Pres. Castello it is stated that during the period beginning Jan. 1, 1916, and ending Oct. 1, the shaft was sunk to the 12th level and a drift run to the main vein. Three hundred and ten ft. west good ore was encountered 100 ft. in depth. It laid in pockets. The vein is strong. Indications are that the body between the 12th and 13th levels will be larger and regular. We did not find pay ore in the north end of the 12th level, but are still drifting on the vein. We opened several flat veins on our 8th level which returned low grade.

Pueblo.

Indications of oil activities in this vicinity have again been revived through the activities of certain interests now attaining land here. Sinking the shaft to the 1360 level has been completed. The distance to the vein is estimated at 330 ft. As soon as the crosscut enters the vein, work of drifting in each direction will be prosecuted. We have also drifted north on our 9th level and are now getting under the flat veins we had on the 8th. Prospects for good ore on the 13th and the north end of the 9th are good. The 11th level

has been disappointing as but one small body was encountered. Development work is still being carried on on this level. Owing to these conditions and extensive development earnings have been small. The financial statement shows the ore sales of the company amounted to \$18,524.05, and that of lessees to \$71,255.96. The total earnings amounted to \$193,859.33 with expenses of \$183,526.31, a net profit to the company of \$10,333.02. The cash balance on hand on Sept. 30, was 98,535.06.

IDAHO.

Wallace.

During the 3 months ended Sept. 31, the Consolidated Interstate-Callahan Mining Co. produced 17,451,243 lbs. of zinc ore and concentrates and 1,454,562 lbs. of lead ore and concentrates, according to the official report of President John A. Percival, under date of Oct. 20. Mill recovery during the period was 85.7% as compared with but 80.99% in the previous quarter, an increase of 4.71%, the result of a more efficient system of treatment and separation that has been incorporated in the milling practice. The net value of the shipments, entrained and ready for forwarding at the point of consignment, was \$655,034, as against \$997,182 for the preceding 3 months, and miscellaneous receipts were \$6030, making the total net income \$661,064, as compared with \$1,004,566 for the previous quarter, a decrease of \$343,502, due to a decline in the price of spelter. The surplus for the period was \$405,726 and the profit was \$413,695, compared with \$713,677 and \$716,348, respectively, for the 90 days ended June 30. Operating costs were \$247,369, a decrease of \$40,848, and improvement costs were \$7968. The shipments consisted of 3297 tons of ore averaging 50.5% zinc, 14,184 tons of concentrates averaging 47.7% zinc, 388 tons of ore averaging 18.9% lead and 1121 tons of concentrates averaging 19.4% lead. The total metal in the shipment was 16,868,836 lbs. of zinc and 1,454,562 lbs. of lead. The combined cost of mining and milling was \$6,302 the ton. During the quarter dividend disbursements of \$1.50 a share, or \$697,485, were made, making \$10 a share, the par value of the stock, distributed since payments were inaugurated on April 1, 1915, and another payment of similar amount probably will be made in December. The new 3-compartment shaft was completed during the quarter to the No. 7 level, and the Interstate vein was opened by a 130-ft. crosscut. Drifting on the lead has disclosed 12 ft. of high-grade zinc ore, showing that the shoot opened on the Nos. 4, 5 and 6 levels continues to depth, and that it is increasing in value as it goes deeper. Referring to the benefits that will accrue to the company by increased railway facilities, the report says: "Construction of the O. W. R. & N. new branch line up Beaver creek will enable us to ship our ore all the way by rail to Enaville, Idaho, where the proposed new mill is to be erected. It also will make possible opening the property on the Beaver creek side, giving us a depth of 3000 ft., 1500 ft. lower than the No. 7 level.

Murray.

Tests of the new mill of the Golden Chest mine were made last week by Supt. Berlin and are said to have proved satisfactory. Because gold and tungsten are nearly the same weight, it was found necessary to entirely remodel the mill in order to save the values. This has been done and new equipment added. Dry crushing has been adopted and two heavy iron rollers have been put in. The ore goes from these to a Trumbull cylindrical screen and thence to the power jigs. Elevators take the ore to the Wilfley tables. Mr. Berlin expects to commence a steady run this week.

Albion.

The Melcher mine, 12 miles from Albion, has lately produced and shipped 50 tons of ore worth \$70 to \$80 per ton. The metals consist of gold, silver, lead and copper. This shipment, which was hand sorted, was hauled to the railroad at Marshfield, a station near Burley. Pere McIntyre, of Salt Lake, is superintendent.

Hailey.

The North Star-Triumph group, acquired several months ago by the Federal Mining & Smelting Co., will begin pro-

duction soon. The new mill, now nearing completion, will handle 150 tons of ore daily, and the output will be transported by wagons to the shipping point until a branch of the Oregon Short Line railway is extended to the property. The group, developed by three tunnels, is credited with production in excess of \$600,000, the result of operations under the ownership of the Philadelphia Smelting Co. "The old lower tunnel, 600 ft. below the outcrop, is 1500 ft. long, and exposes a body of complex lead-silver-zinc ore several hundred feet in length and from 10 to 15 ft. wide," says Robert N. Bell, state mine inspector, in a recent report on the property. "A large part of the production was from below this level, from which a winze was sunk 200 ft. on the shoot and drifts run every 100 ft.

LAKE SUPERIOR.

COPPER.

Houghton.

Mohawk has increased its shipments to nearly normal and its tonnage for October will be about 63,000 tons which at 19.5 lbs. a ton will yield 1,239,500 lbs. There is every reason to believe that the figure for November will be the capacity of the mill, about 68,000 tons.

Wolverine will gain this month in its tonnage. For October it had 27,000 tons, but it is gradually increasing its number of men. The normal for this mine is about 36,000 tons monthly. The production in refined copper for October is about 465,500 lbs.

Michigan has found the width of the Evergreen lode to be about 48 ft., of which the first 25 ft. disclosed only occasional specks of metal, the next 15 about 300 lbs. of small mass, which made this strip probably of commercial value, and the 4 ft. following were like the first and were succeeded by 2 to 3 ft. of trap and 8 ins. of a greenish decomposed epidote which carried considerable copper and lay quite flat to the dip of the preceding parts of the lode. The copper bearing strip is most promising. It will be developed by drifts as soon as the main crosscut on its way to Nos. 1, 2, and 3 of the North lodes of the South lake has progressed sufficiently so as to be out of the way. The drift on the Ogimah lode is getting a fair grade of stamp copper and the eastern drift from the Butler lode which is being pushed up to the 5th level in the longitudinal fissure lying just above the lode is now running into a good quantity of mass copper such as has been abundantly met with here. It seems likely that one or more lodes of profitable grades will be encountered by this crosscut and that eventually a good sized and profitable production will be made.

Calumet & Hecla ceased work Election Day and offered those who worked Monday and Wednesday full pay Tuesday. The production in October was nearly up to the average of 10,600 tons daily, and that of the entire district was considerably better than in September with the same number of working days. Mohawk was close to its normal, Isle Royale was better than ever, Hancock pushed forward notably, Osceola rose fast at the last of the month, and the others increased slightly or at least held their own, and some of them, as the Quincy and Copper Range, are about up to the top notch. The present month will have a better daily average and probably will ship more rock than was milled in October. Men are staying better and there is a fair supply coming in steadily. The copper is going out as fast as possible by boat to save the extra cost of rail transportation, as it will have to be delivered as soon as it is ready and therefore none can be held over for the spring. There are about 13,500 tons of copper that will be taken from the 11th to the 30th by the Great Lakes Transit line, the limit of insurance expiring on the last named date.

Lake is driving crosscuts from its shaft on the Knowlton lode over the Butler on the 4th and 6th level, a distance of about 400 ft., because the latter is known on the whole to be the richer. The Butler is being mined at the Mass, South Lake, Michigan and the Indiana, and at the two first is producing highly profitable rock, while at the third the showing is good, and at the last it has only just been opened,

and should show value here just north of the South Lake where its copper is of heavy grades give pleasing disclosures.

Cherokee has drifted 30 ft. each way in as good copper as has been passed through, the small mass and barrel predominating as usual; it will not crosscut on the lode so as to get its width and mineral contents. An efficient crew has been gradually taken on and the work is progressing at a good rate.

South Lake has been getting a large amount of mass from the Butler lode, one piece weighing about 6 tons. The lode, ever since it has been opened at this property, has had a remarkable amount of mass, both large and small, and is so far the best of the seven South Lake lodes. It is being drifted on in both directions and is sending quite a steady quantity to the Franklin mill, the rock being all from the drifts which are quite uniform in values. The tonnage is being steadily increased, and will be enough to yield considerable profit as soon as the new houses that the company is building are ready for their families. The lack of houses for families has been a great drawback.

New Arcadian is finding some excellent grades of rock on the southern drift of the 1050 level at quite a distance in from the shaft. The track has been shifted over for the new rockhouse, and in a short time all will be ready so that the underground work can be pushed.

New Baltic is down 42 ft. with its shaft pit and is putting in the timbering. After this task is finished, sinking to the ledge will be resumed. The top of the ledge should be cut into at any time.

Flint Steel has been pumping out its old shafts on the Butler lode for the past week. The owners of this option have all the money that is necessary to explore this property and will probably thoroughly ascertain its mineral values before giving the public an opportunity to participate.

Houghton has discontinued the exploration of the West vein that has been so rich at the Superior and has put the drill to work on the bottom of 12th level of the winze. The West vein showed its characteristic rock but not its characteristic copper and consequently no more work will be done on this level, but later if the winze or the shaft is carried down further undoubtedly it will be opened again.

Winona is working its shafts, Winona No. 4 and King Philip No. 1, both shifts, but has not yet been able to get the men for the night shift at Winona No. 3.

Osceola had a tonnage of 113,800 for October which is the largest for 3 months and is some days running to its mill capacity nearly 4700 tons since it has been quite successful in getting the men it has been needing. It will be soon running up to its normal about 119,000 to 120,000 monthly. A few men have been taken on all around but the most at No. 3 North Kearsarge.

Hancock produced in October 408,836 lbs. of refined copper from 24,782 tons of rock with a yield of 16.50 lbs. a ton, a rise from that of 15.16 in August. The most striking fact is net earnings of over \$42,000. This is sufficient to show what will be achieved in the future when the ground at both shafts is opened up for a large production, the construction costs for quite a while ahead having been provided for. It is probable that the production can be made large enough while the metal is soaring in price so that the costs will be quite low when the prices begin to drop. Men are the great want here now. They are coming slowly and are staying better than before as they are looking for good jobs for the winter.

Keweenaw is still unable to work its mill all of the day shift for the lack of trammers, having only 11 to 12 when it needs 24 to 25, consequently it will be some time before it can start the night shift. Only about 1000 tons had been milled up to Sunday the 5th; and therefore the management will not publish the mill run until a much larger amount of rock has been stamped, especially when it has so much on the surface in the stockpile. It is known that the rock in its recovery is equal in yield to the average of the lower grade mines of the district.

Isle Royale has completed enlarging to full size the shaft, which had been at first only holed through by raises,

and has now begun to sink. Some kind of a makeshift rock-house will be provided soon so that the good rock here, that has been so abundantly met with in the cutting out of the shaft can be added to the mine's production. The tonnage is constantly over 3000 tons daily.

Indiana in its shaft on the lode thought to be the Butler down about 85 ft. from the surface, or about 60 from the top of the ledge which is at the bottom of an old trench, and is finding some copper ore and occasionally bunches that are of a commercial value. The width of the lode is apparently quite good. A crosscut will be driven both to ascertain this figure and explore the lodes where there are the usual members of the Knowlton and Evergreen series.

IRON.

Virginia, Minn.

Work is being commenced by the Oliver Iron Co. on 4 forties known as the Missabe Mountain property. Drilling has been prosecuted on the property for the past year and it is said that sufficient ore has been proven to warrant 25 years' work. From 1 to 3 shovels will be engaged in stripping to be undertaken this winter. Tracks and making of grade is now being worked on. Trestles for the stripping material are also being built.

Crystal Falls, Mich.

The mines of Iron county are carrying considerable more ore over in their stock piles this season than was expected. There are large piles at the following mines: Great Western, Bristol, Carpenter, Tobin, while at the Dunn and Odger mines the piles have been entirely cleaned up.

J. M. Longyear, Jr., is now doing exploratory work in this district and it is said that J. M. Longyear, Sr., is intending to take over and reopen the Mansfield mine.

Ashland.

Attracted by the finding of lines of magnetic attraction by State geologists, work has been started again for the purpose of locating commercial bodies of iron in northern Wisconsin. The most recent developments are in the region east of Hayward. A drill in that region will start operations within a few days. It is understood to be owned by the Edson interest of Duluth. Other syndicates are also reported to be in process of formation for the purpose of carrying on exploration.

Biwabik, Minn.

Because of excessive costs and greater amount of water at depth but little diamond drilling is being done in this district. The Ruddy mine which filled with water during the strike has been closed and the owners say it will remain idle until mines in that vicinity assist in lifting the water from the basin in which it is located. It has considerable ore developed.

Iron Mountain, Mich.

Stripping has been finished at the Antoine and the company now has several million tons of ore exposed and during the winter will employ a considerable force in development. The work will include a 2-track drift 500 ft. long and the opening of five more "mills" from the bottom of the drift to surface.

MISSOURI-KANSAS.

Joplin, Mo.

A jump of \$10 a ton was recorded in blende for this week over last week's high price, and \$90 was paid for first-class zinc ores, with an average price of \$82.50. While the situation as to the electric current has not been entirely cleared up, most plants are resuming operations that have been forced to close down.

A good strike has been made by Lackey and associates on a lease of the Stokes-Shoemaker tract of the Missouri Lead & Zinc Co. land, southeast of Joplin. A shaft that is being sunk by the company went into ore at 155 ft. Drill hole records showed a good face of ore at about the depth in which the shaft of the company showed ore at the 155 level.

Several rich mines have been opened in the vicinity of this new mine. The Bumble Bee Mining Co. has a shaft in rich ore less than 100 ft. east of the new shaft and 3 shafts in other sections of a tract, which are all in good ore. This company is also completing a new 150-ton mill.

Excellent dirt is being brought out of the Tuxedo Mining Co.'s property on West Seventh Street, just east of the Paragon mine. There is a face of rich dirt 33 ft. high by 20 ft. wide developed. Last week 100 tons were milled and an output of more than 10 tons of high-grade blende resulted. The Tuxedo is one of the J. M. Short properties, and a mill is planned for it in the near future.

The Joplin Ramage plant resumed operations Nov. 11. This mine had been closed down for the past 2 months. It is one of the best properties in Joplin, the mill having a capacity of 1000 tons per day. Work is carried on in a sheet-ground formation at a depth of about 175 ft. H. H. Hartzell is superintendent, having formerly had charge of the Granby Mining & Smelting Co.

The Kenefick Zinc Co. is making steady progress on their new shaft north of the Coyote Mine in West Joplin. A depth of about 80 ft. has been made and most of the way has been extremely hard. The ore formation is expected to be about that which is now being mined successfully by the other Kenefick companies to the south, the Coyote and the Airedale.

Eakman & Co., on the Gregg land in Jackson Hollow southwest of Joplin, are developing a mine that looks promising. The company is composed of relatives. They are Riley, Alex, Arthur, William and Harvey Eakman, all of Jackson Hollow. Operation was started a month ago. The property is on the same ground as the old M. I. & O. mine, which several years ago was one of the biggest producers in the Jackson Hollow camp.

Webb City, Mo.

Not only is the bonanza face of rich sheet ground ore opened up some 3 weeks ago at the Evans-Hall-Soy mine at Duenweg continuing as rich and promising, but another good strike has been made in a drift to the north of the mill.

Cartersville, Mo.

Operations have been started at the Mont B. Mine, north of Cartersville, after a shut-down of about 2 months. The drifts were drained and men put to work in the drifts early this week. Twelve new sludge tables have been installed and new engines substituted or added to those already in use, and the mill building was overhauled and enlarged.

Galena, Kans.

Good production is being recorded at the Wayland mine, at Galena. Last week the total output from the tract under control of this company was 150 tons of blende and 5 tons of lead. The construction of the Murphy flume is gradually bringing back into the producing column many properties that were put out of business by flooding.

The Lone Elm ground is now being completely opened as a result of the rebuilding of the Murphy Flume. Also, the Premium Mining Co. just got into the ground again last week, after a long, hard fight with pumps, and several small subleasing companies are getting busy once more.

The Mustain Mining Co. is having good success with mining operations at Cave Springs where it has a lease of the Hartley land. This company recently did away with its horse hoister and has installed a complete steam rig. J. W. Mustain is general manager.

MONTANA.

Butte.

The Mines Operating Co., said to be connected with the Guggenheims, has been formed to operate the Butte Duluth, and have a 5 years' lease on the property. The president and general manager will be Al Frank, Salt Lake; Charles W. Whitney and E. L. Newhouse, Jr., Salt Lake, and John MacGinnis and H. A. Frank of Butte will assist the president.

Whitney will be vice president and E. L. Newhouse, Jr., secretary.

Bannack.

Machinery is now being shipped and installed at the Original Bannack. The main shaft is to be put down to the 300 level. John F. Cowan is in charge. The miners have opened at a depth of 150 ft. a 50-ft. vein that carries 1½ to 2% copper and \$2 in gold. There is such an unlimited quantity of this low-grade ore already demonstrated, said Mr. Cowan, that the blocking out will be continued during the winter and the management of the company will arrange for the erection of a plant early next year.

Corbin.

G. F. Ferris has ground which is producing Danish pebbles used in various types of revolving crushing machinery at mills. They were \$10 per ton before the war, but since have gone up to \$33. Ferris is selling the pebbles at \$30 per ton.

Wisdom.

It is said that the Saginaw is now the only mine in the district operating on a paying basis. About 8 tons of high-grade ore now being shipped daily.

Clinton.

In reporting on a recent strike of bismuth here, Fred G. Bond, Missoula, Mont., says: "The vein is 6 ft. wide. It is composed of crystalline matter in banded form containing metallic bismuth. The dimensions of some of the larger cubes are ¼ by ⅛ by 1-16 of an inch. Ore was drifted on 45 ft. before discovery of bismuth. It was at first mistaken for lead-silver ore. The hanging-wall is quartzite and the foot-wall Butte granite. About 2 tons are on the dump. The apex of the vein is traceable for 2000 ft., and the property is owned by W. H. H. Dickinson and myself."

Saltese.

H. M. Lancaster, retiring superintendent of the Richmond states that about \$1,000,000 in ore is blocked out. The values are higher than indicated by an early sampling. This is shown by returns on shipments, 1 carload having been settled for on a basis of 15½% copper, yielding \$1300 after the deduction of treatment and transportation charges. The returns include gold, which runs \$4 to \$5 a ton. Seventeen cars shipped between Sept. 13 and Oct. 20 brought \$20,000 net. These shipments were made from the upper level. The block probably contains 10,000 tons of ore of 10% copper, while there may be as much more in value between the upper and lower levels. There is probably \$400,000 net above the upper level. The lower level, which opens on the Idaho side of the property, has been run to a point under the shaft, where a depth of 320 ft. is attained, and lacks only a short distance of connection.

Superior.

At the annual meeting of the Intermountain Copper Mining Co., held in Spokane on the 2d, Edward Evans was elected president, W. J. Griffith, vice-president; Harold M. Childs, treasurer; Harve H. Phipps, secretary, and Oscar Nordquist, general manager. The officers also compose the directorate. A dividend of a half a cent a share, or \$8250, was declared, payable Nov. 20 to stockholders of record Nov. 10. This is the second dividend by the company, one of equal amount having been authorized for Oct. 20. The company owns and is operating the old Amador mine and recently contracted its output to the B. C. Copper Co. at Greenwood, B. C., securing a very satisfactory rate. Its new mill, a 100-ton daily capacity plant, is in service, and reports state there is sufficient ore to keep the plant supplied for from 3 to 5 years.

NEVADA.

Goldfield.

The shaft of the Silver Pick has gained a depth of 1100 ft. and for about 200 ft. has been in a broken formation largely consisting of quartz. Intrusions of alaskite and shale have been numerous, and several seams of rich ore

have been intersected. A station is being cut and preparations made for extensive crosscutting to the west.

Goldfield Con. reports new equipment for the 1000-ton flotation plant in transit, and installation of the additional thickeners and filters will begin shortly. The underground electric haulage system is complete, and with the flotation plant in commission all ore will be hoisted through the Combination and Clermont shafts. Late development work in the lower workings has been satisfactory.

Rochester.

An agreement has been ratified between the Rochester Merger and Nenzel Crown Point companies, whereby the latter is permitted to develop its holdings through the Pitt tunnel of the Merger. A crosscut will be driven from the tunnel to cut through Nenzel hill, and is expected to intersect a series of promising shoots, that have been indicated by surface prospecting. A substantial interest has been purchased in the Rochester Merger by Clyde A. Heller, president of the Tonopah-Belmont Co.

Bullionville.

The new mill of the Prince Con. is making a satisfactory gold and silver extraction. The plant has a rated capacity of 100 tons and the management states 120,000 tons of tailings are available. Milling tests indicate the material will net approximately \$5 per ton. Some difficulty has been experienced in removing the weeds that have grown luxuriously on the old dumps, and a tube-mill has been provided to remove the weeds and reject them from the mill feed. The mine, at Pioche, is shipping about 400 tons daily, with developments keeping reserves well ahead of extraction. President A. H. Godbie has just concluded an inspection of mine and mill, and expresses himself well pleased.

Las Vegas.

Important development in Eldorado Canyon recently is the discovery of platinum on the Eldorado Enterprise G. M. Co.'s property.

The first assay for platinum was made by H. H. Wheeler, Needles, California. The second assay was also submitted to Wheeler for a check and was found to carry 0.20 oz. platinum per ton, or \$20.10. Much higher assays are anticipated as the samples referred to were mostly surface ore from the gold bearing ledge. Assays from this property showed also good values in gold and silver.

The property has a well defined ledge. It is opened for intervals of 500 ft. along the vein. E. P. Jeanes is president.

Ore carrying values high in gold was uncovered on the Woods lease which adjoins the Carnation claim. The body is an extension of the Carnation and promises to be quite as interesting.

The recent strike on the Carnation cannot be over-estimated. Spencer, Kerchener and Welk, leasers, now have assays which show good values per ton in gold and silver and increasing in value as development proceeds. The general samples across the ledge, which is now 4½ ft. wide, are said to show high values in gold and silver.

German, Fisher & Herman, leasers on the Lombard claim which adjoins the Carnation are now securing figures preparatory to installing a stamp mill and cyanide plant in the near future to mill their ores taken from this property.

Spencer, Kerchener and Welk have taken a bond and lease on a group of claims adjoining the Quaker City Mine, a large producer of gold in the past. The Quaker City belongs to the Wharton Estate. A company known as the Fifth Avenue Gold Mining Co. is now in the process of organization. E. P. Jeanes, owner of the McKinley Group, is erecting new camp buildings on this property. Several new leases have been taken by parties from Good Springs and elsewhere during the past week.

Tonopah.

Sinking of the Victor shaft of the Tonopah Extension is proceeding satisfactorily and lateral work from the new level will begin shortly. On the 1540 level stoping is proceeding on the Murray and North Merger veins.

Denio.

Numerous improvements are being made at the Ashdown mine, a few miles southwest of Denio. The mill is crushing

40 tons daily, and its capacity will be doubled soon. The 2-mile pipeline is being covered and other precautions taken to prevent interference by winter storms with activities. Good ore is coming from a number of levels. Operations are carried on by way of tunnel No. 10, the main working level. The 10 different tunnels are all connected.

Rawhide.

The ore body lately encountered at a depth of 650 ft. in the Nevada New Mines group continues to develop splendidly. It was struck in the drift from the Victor shaft and has broadened from its original 12 ins. to 4 ft. It is largely of sulphide character with assays averaging around \$60. Silver is largely in the predominance. At several other points in the property good ore is being mined and the outlook is decidedly good. The two mills are running at capacity. The group forms a merger of the Rawhide Queen and Rawhide Coalition mines.

Late discoveries in the Nevada New Mines property, formerly the Rawhide Coalition and Queen mines, have been particularly satisfactory. Near the 600 point the Victor and Phoenix veins have formed a junction the ore is being followed by a winze. Gold-silver specimen ore shows, and the general run of mill ore is stated to be averaging around \$15. In the Black Eagle mine a strong shoot of \$13 ore, 2 ft. wide, has been struck near surface in virgin ground. The 20-stamp Black Eagle mill is running on ore from both properties. E. W. King is manager.

Gold Mountain.

Thomas Grimes and Gus Hansen have started shipping from their lease on the Tonopah Divide mine to the West End mill at Tonopah. The ore is coming from the tunnel at a depth of 100 ft. and averages around \$40 in gold. The first shipment contained 50 tons. Several properties are being worked in this locality and indications are considered promising for development of a number of producers. Most of the work is done by lessees.

NEW MEXICO.

Santa Rita.

The September output of the Chino Copper Co., 7,397,000 lbs., notwithstanding a short month, represents an increase of 1,000,000 lbs. over the August production, and 2,000,000 lbs. over the corresponding month a year ago.

With the inauguration of a new and more extensive plan of development the Santa Rita Development Co. is having its property examined by Walter Harvey Weed. In connection with development considerable diamond drilling will be done. The capital stock of the company is \$1,000,000. Of this amount 300,000 shares have been underwritten and sold. H. W. Loomis is superintendent and James E. Suits has been elected secretary and manager. Suits was the original promoter of the El Tigre gold mines in northern Sonora, Mexico.

Lordsburg.

Development through No. 3 shaft is to be commenced at the Bonney Co.'s mine which was recently taken over by Chicago capitalists. The company was incorporated as the Western Mining & Development Co. Most of the stock is held by D. J. Evans, Chicago. Development will be continued at the 4th level and a drift run to connect with the No. 2 shaft. Crosscutting will be done and underhand stopes raised from the 4th level. Hoisting will be done from the lower station. The company has closed a contract with the Copper Queen smelter, Douglas, Arizona, for the shipment of 1000 tons monthly. In order to hold to this mark the company plans to block out ore at all possible places.

Mogollon.

Socorro Mining & Milling Co. shipped 23 bars of gold and silver bullion from clean-up for last half of October, a total of 41 bars or a little over 2 tons for the month, from a reduction of 7000 tons of ore.

The product of Mogollon Mines Co. for latter half of month was 13 bars gold and silver bullion, making 28 bars for October, from a treatment of 4100 tons of ore. In addition,

several tons concentrate were shipped to Smelter at El Paso.

The Oaks Co.'s last shipment of ore to custom mill from exploratory work on Clifton mine indicated a value of \$14 per ton. This rock came from the Queen Vein and emphasizes the latent possibilities on this lode that may be expected from adequate and systematic development.

At the Gold Dust properties, on which work was lately resumed, the main tunnel is being retimbered and raises and drifts extended.

Earl C. Cleaveland, who for some time has been acquiring data relative to hydro-electric power possibilities in this locality, has just returned from West Fork of Gila River, where he and associates have run surveys and taken water readings over a period of two years. Thus far the average flow found, under available head, if sufficiently developed, will take care of both present and prospective power requirements of the district. When some such project is consummated the camp will be able to treat profitably an almost unlimited tonnage of low grade ores that otherwise are unavailable under present high power costs.

Lee's Peak.

The Oete Mining Co. has contracted with Wright Bros. to sink a shaft 570 ft. on its property near Lee's Peak, work to begin at once.

SOUTH DAKOTA.

Hill City.

The Hill City mill is now handling ores left in the bins of the Harney Peak Tin Co. as well as custom tungsten ores. A fair extraction is being made and a run of this ore resulted in cleaning up 1500 lbs. of tin concentrates. The company has erected a smelter near its mill which has commenced successful operation.

The immediate reopening and further development of the Gladiator and Pennsylvania mines is being rumored. It is also stated that the owners of the Gladiator intend erecting a mill.

Custer City.

At the Golden West 200 ft. of crosscutting has been completed. The company will now drift about 150 ft. south and then resume crosscutting. Work was started in the spring. At 400 ft. from the portal the foot-wall of the vein was encountered. Further west the ore-formation was encountered, but as yet the hanging wall has not been reached. The south work will be in the direction of, and eventually immediately beneath, the open-cut from which several thousand tons of ore have been milled.

Keystone.

According to Superintendent F. H. Gira of the Cuyahoga Mining Co., development work has been completed and production started. The ore is sent to the Cleveland Chemical Co., Cleveland, O., and treated for sulphuric acid. It is said that the entire output which runs over 40% sulphur, has been contracted for.

TEXAS.

Terlingua.

Several new cinnabar claims in the Terlingua district are to be developed as soon as the necessary equipment can be brought in and installed. It is stated that a syndicate of Houston men, headed by Morris Wexler, has acquired several sections of land in this part of the Big Bend region upon which there are outcroppings of cinnabar. It is expected that within a short time all of the mines at and near Terlingua which were idle for the last few years will have been placed in active operation. While the principal output of quicksilver now comes from the furnaces of the Chisos Mining Co., of which Howard E. Perry of Chicago is president, several other companies have resumed development work and are getting out considerable quantities of rich ore. The

principal mines are those of the Chisos Co., Mariposa Mining Co., of which James Normand of Marfa, Tex., is president; Texas-Almuden Mining Co., of which Henry Hill of Clifton, Ariz., is president; Study-Butte Mining Co., of which W. B. Burcham is manager, and the Big Bend Mining Co.

Outcroppings of cinnabar ore have been discovered to the east of Terlingua about 60 miles; but, so far, no steps have been taken towards their exploration or development. The quicksilver belt also extends across the river into Mexico from Terlingua. At the time the revolutionary period began in that country several promising claims of cinnabar had been filed upon and were about to be developed.

Sierra Blanca.

The Southwestern Mining Co. is developing a zinc, lead and silver mine near here. It has been making regular shipments of ore to the smelter for some time past. In the 300 level a large body of ore that runs high in lead and zinc and about 50 ozs. of silver was encountered.

Toyah.

The West Texas Sulphur Co. is preparing to exploit two large sulphur deposits which it owns near here. It will install retorts for the treatment of the sulphur-bearing material and a plant for refining the product. It is stated that the beds of sulphur outcrop upon the surface and extend down to unknown depth.

Van Horn.

A. D. Hudson of El Paso and associates, who own a large deposit of turquoise, situated near here, are producing considerable quantities of the gems.

Austin.

The large deposit of celestite ore which is located about 3 miles from Austin may be developed in the near future. It is owned by Judge R. C. Walker of this city. He plans to install a plant for the mining and utilization of the ore.

UTAH.

American Fork.

With the completion of the electric power line to this camp by the Utah Power & Light Co. a new era in mining is expected and it is said that no less than 18 properties will operate through the winter. The line will first be run to the Pacific mine, under bond and lease for 10 years to the Fissures Exploration Co., and also to the mill built by the company on Dutchman flat. The mill is now practically completed.

At the South Park two tunnels are being driven and these will be equipped with power drills just as soon as the power reaches the camp. Some high-grade samples of lead-silver have been found, and the officials of the company are confident that they have the continuation of the Pacific fissure.

The Earl Eagle property has its tunnel in better than 500 ft. and expects that the Miller fissure will be encountered soon.

The Beck Tunnel is in 130 ft. Within the next 70 ft. it is expected that a large ledge will be cut. The front tunnel, which is closed to the Pacific mine, is in 110 ft. It is expected that it will reach its objective in about 200 ft. This work has been stopped until the power line is in.

Garfield.

Into the present tailings pond there has been dumped 50,000,000 tons, besides something like 1,500,000 tons of waste. The latter was used in making the embankment.

The tailings from the Arthur and Magna plants are to be retreated. In behalf of this work part of the \$2,500,000 set aside by the Utah Copper Co. for improvements will be used. The new tailings pond will include 1400 acres located north of the existing tailings pond. Buildings and structures are now being moved to make way for the new pond. With leaching and new methods of concentration it is believed that the tailings can be treated again at a profit. The old pond contains 3500 acres and is 3¾ miles long by 1½ wide. The embankment is from 12 to 20 ft. high and it was figured that the ultimate height would at some time reach 80 ft., which

would be equal to two square miles covered to a depth of 90 ft.

Park City.

Judge Smelting & Mining Co. is now developing and blocking ore between the 900 and 1200 levels. The ore was first opened up on the 1200 level. It has been followed for 300 ft. Raises were run on the ore to the 900 level and there the ore continues up. It is a high-grade milling ore, much of the value being in zinc, and if it were not for the high percentage of zinc, much of it could be shipped direct. It varies in thickness from 15 ins. to 15 ft. About 4000 ft. from the shaft a splendid body of ore is being developed above the 1200 and has been followed for 250 ft. Preparations are being made to extend the shaft to the 1900 level. At present it is down 1650 ft. It is the intention to raise from the 1900 level, which is opened up through the Daly West.

At the mill all the steel work is completed and machinery is being installed, which, when in operation, will be run by electricity.

The Broadwater mill has resumed operations on tailings, the installation of new machinery and remodeling having been completed.

By flotation it is shown that the savings on the tailings at the Big Four can be brought up to 90% as compared with the present savings by table concentration of around 60%. The company has also been making tests with an electrolytic process that also shows a saving of better than 90%. In a short time one of the new methods will be installed. The tailing beds have been thoroughly sampled. They were laid out in 100-ft. squares and a sample taken at each corner. About 1000 samples were taken. The samples show 4.1% zinc, while the mill run shows it is about 1% higher than the samples showed. About 800 tons are now being treated daily.

Eureka.

The North Lily Co. is intending to immediately start a shaft on the Wicklow property which is part of its ground. Work done some years ago proved a good vein but greater depth will be attained before exploring this vein.

A new shaft, for the completing of which it will take about 7 months, has been started at the Tintic Standard. The shaft will be 3-compartment and will be sunk to 1300 ft. The site of the shaft is 1700 ft. northeast from the old 1000-ft. shaft. Production of the mine in October was 12 cars, bringing \$1400 to \$1500 each. The values are mainly in lead and silver. A blower is being installed to give better ventilation in the lower workings, where a body of commercial ore is being developed.

Sinking on the recently encountered fissure at Sioux Con. is progressing, and the fissure seems to remain as when first encountered. The winze has reached 100 ft. below the 600 level and sinking is still in progress. Owing to the scarcity of men the company is using but one shift but as soon as possible the force will be increased. Contractors, Duncan & Allen, have put the shaft down about 60 ft. since work started Oct. 17. They are using three shifts.

The South Standard Mining Co., recently formed to take over ground of the old Montreal Co., will commence work on a vein which was encountered by the latter company while driving a 500-ft. tunnel.

Milford.

Beaver Lake Metals Mining Co. is developing in the Beaver Lake district, northwest of here, a group of 12 claims. On the property is an east-west contact between monzonite and limestone. Operations are in the lime, where there is a fissure running parallel to the contact, 150 ft. north of it; and from this fissure there are lateral veins cutting northward through the lime. Present development is confined mostly to one of these lateral veins. An inclined shaft was sunk 90 ft. in ore, and exploration from this showed a vein of well mineralized gangue, from which some ore is being shipped, running about 62% lead, 30% iron and 20 ozs. silver. To operate to better advantage, a working shaft was sunk 150 ft. on the west side of vein. By crosscutting 200 ft. east from the bottom of the shaft to the vein gives a depth of 200 ft. on ore. The crosscut is about completed. Power is supplied by a semi-Diesel engine, which drives an air com-

pressor, and the two hoists over shaft and incline are operated by compressed air. The property is under the management of Lewis Merriam, also manager of Yankee Con. in Tintic district.

WASHINGTON.

Spokane.

The Coeur d'Alene Mine Owners' Association, of which Stanly A. Easton, general manager of the Bunker Hill & Sullivan Mining Co., is secretary, will install a comprehensive display of the minerals of the northern Idaho district in the new quarters in the Spokane hotel of the Northwestern Mining Men's Association, a reorganization of the Spokane Mining Men's Club, the pioneer society in the northwest of men interested in the mining industry. The association has taken a long-term lease on a ground floor apartment in the Spokane hotel building, adjoining the Silver Grill, and connected with it, and is fitting it up as a permanent home for the organization, where open house will be maintained for visiting mining men. Several thousand dollars will be expended renovating the quarters and furnishing them, and the formal opening will take place on the return of the Spokane delegates to the American Mining Congress convention in Chicago. In a letter to President Graham B. Dennis and Secretary Frank C. Bailey of the Northwestern Mining Men's Association, Secretary Easton states that the Idaho Mine Owners' Association has subscribed funds to provide three mineral cabinets in which to display specimens from the Idaho mines. A check for the amount accompanied the communication, and Secretary Bailey was authorized to purchase the cases. "The purpose of the Northwestern Mining Men's Association is to bring into closer relationship the mining men of the different districts in the surrounding territory and to endeavor to secure legislation, both state and national, beneficial to the mining industry," said Secretary Bailey. "Our membership includes all the prominent mine managers and owners and all the reputable mining engineers of our jurisdiction, and in addition there are scores of bankers, business and professional men and newspaper men, a combination of interests that assures representative influence in any movement we may inaugurate."

Republic.

The Lone Pine-Surprise Mining Co. is preparing to begin sinking a 500 ft. shaft on its Last Chance claim, and a 5-drill compressor, hoist and a 100-hp. boiler have been ordered for the work. The contract has been let to C. S. Cox and J. E. Henwood of Kellogg, Ida., and sinking will begin as soon as the machinery is delivered and installed. The Last Chance has been entered from the workings of the Insurgent mine, adjoining, and the ore bodies have been proven to the 540 level. It is believed that the Insurgent vein, from which several hundred thousands of dollars worth of ore were extracted by leasers and option holders, dips into the Last Chance lines, and the company plans to explore the ground thoroughly from the proposed shaft. The Co. is a Spokane corporation, and the most of the stockholders are residents of the Inland Empire. Sufficient capital to finance the development planned already is available, and it is believed that the property will be placed on a producing basis again in the next few months.

Chewelah.

Under C. F. Weist the Silver Queen group is to be exploited during the winter months. Jake Schoenberg has also taken a crew in to explore the ground of the Silver Antimony Co.

The Blue Star lead-silver mine has been leased to Spokane interests. Heavier equipment has been installed at the Juno-Echo and will sink to 150 ft. Conditions have been improved and the shipment of several cars of copper has been made. The company is said to have a good treasury fund. This, with the returns on further shipments, is expected to provide all of the money for development.

Since completion of its shaft to the 500 level the Security Copper Co. has cut a station there. Sinking was resumed with the 550 level as the objective. It is believed

the additional 50 ft. will care for the water when the veins are crosscut without the addition of other machinery. Two shifts are engaged.

Casper.

The Midwest Oil & Midwest Refining companies recently purchased a half interest in the production of the Elkhorn for \$25,000, besides agreeing to put down four shallow wells, the aggregate expenditure of this being an additional \$5000.

Recently the Elkhorn Oil Co. brought in its second oil well on the north side of Platte. The sand was penetrated by the Green Distilling Co. at a depth of 938 ft. and was drilled into only 11 ft. The well filled immediately with a fine quality of light oil, and did so in such a short time that it was necessary to pull the tools. Tankage capacity is being rushed to the scene. The oil from the well is temporarily run into tankage south of the river to prevent loss.

Colville.

The Surprise mine of the Walla Walla Copper Co. is to be opened soon. Manager Malin says: "As soon as the power plant is tested out, a transmission line will be constructed to the main workings of the mine where an engine house and a new blacksmith shop is now under construction. The property will be equipped with a compressor, electrically driven, machine drills, hoist, etc. The adit tunnel will be wired for electric lights and the station at Surprise shaft will be enlarged for the construction of a head frame. The ore deposits will be developed from the Surprise shaft, which will be sunk to the 100 level and crosscuts run. The mine will be operated with two shifts within the next month."

WISCONSIN-ILLINOIS.

Highland.

Saxe-Lampe Mining Co. shipped 1 car to Mineral Point Zinc Co. and 1 car mixed blende to National Zinc Co., Springfield, Ill. The Eagle-Picher Lead Co. closed on several lots of carbonate zinc, 3 cars, 112 tons.

Platteville.

Delivery of ore for the month of October was shown as follows: Zinc, 4,525,400 lbs.; lead, 766,000 lbs., and pyrite, 6,408,000 lbs. The gross recovery of crude concentrate was much lighter than usually reported, 35,640,000 lbs. being reported for the month, while net deliveries were fair, the total clearing the field going 25,580,000 lbs. The Mineral Point Zinc Co. delivered 70 cars of high-grade separator ore to smelter at DePue, 5,232,000 lbs.

Returns for the field for week of Nov. 11 show deliveries of 140 cars of zinc concentrate, 5407 tons. A feature of the week's buying was shown in the sales made to the Eagle-Picher Lead Co. which managed to secure secure 23 cars of choice ore, 1012 tons, some of which had been carried for months. Among the lot was mixed lots of high grade carbonate zinc ore. Shipments of lead were light, only 2 cars being sold, 69 tons. Shipments of pyrites also showed up poorly in the face of higher prices for acid and a better demand for ore, 654 tons clearing. The gross recovery of crude ore for the week was 4453 tons; net deliveries to smelter 3513 tons. Mineral Point Zinc Co. to DePue 14 cars high grade, 518 tons.

A sharp gain in price of blende was noted at the outset of the week, the base jumping from \$75 to \$85 per ton for standard and premium grades of ore with the range down to \$80 for medium and second grades. A better demand was shown for low grade concentrate much of which found its way to separating plants from independent producers. Lead ore was bid up to \$87 per ton base of 80% metal content.

The West End Mining Co. is driving a level into the hillside on lands west of the Klar-Piquette mine both to drain the property and open up a deposit of zinc recently proven and said to be 6 ft. thick.

Shipments from Platteville mines were limited, the Klar-Piquette sending in 1 car recovered from tailings re-milled.

Hodge mine to Cuba 3 cars, 131 tons. Block-House Mining Co., running on medium grade mine run ore is operating its own separating plant and last week shipped 3 cars of 62% blende to Edgar Zinc Co., 118 tons and 2 cars to Eagle-Picher Lead Co. smelter at Collinsville, Ill.; 80 tons.

Linden.

The Milwaukee-Linden Development Co., which closed a deal 2 weeks ago for 1000 tons of concentrates cleared 8 cars last week to Mineral Point, 248 tons. Optimo mines to local refinery 2 cars, 80 tons; Linden Zinc Co. high-grade to Eagle-Picher Lead Co., 40 tons; Ross Bros. to Mineral Point, 30 tons.

Active resumption of zinc ore refining by the Linden Zinc Co. called out 13 cars of ore from nearby mines, 495 tons. Two cars high-grade blende were shipped to smelter, 80 tons. Ross Bros. mine, a consistent producer for 10 years, is reputed to have nearly run its course. Heavy pump equipment is being installed at the Weigle mine for the Milwaukee-Linden Development Co.

The splendid showing made here the first half of the year has been followed by an apparent season of depression. Shipments of zinc ore are light and much ore is held in bin and prospects from the market standpoint are not bright. These drawbacks do not discourage new projects, two of which, recently developed and equipped, are now in running order.

Miffin.

A better condition prevailed last week regarding shipment of zinc ore, all independent producers being accounted for with one car each while the Coker mines made their usual showing 7 cars to Mineral Point, 280 tons. Local producers in the Barreltown district delivered small lots to furnace, 30 tons in all.

Montfort.

The O. P. David mine, in charge of Theo. A. Waesch, Supt., is now in splendid operating order, running on sharp shift of the range toward the north and producing steadily. Two cars of 55% ore were shipped to M. & H. Zinc Co., LaSalle, 80 tons.

Shullsburg.

Rodhams Mining Co. shipped 1 car high-grade jack last week to Lanyon Zinc Co., 41 tons; the Winskill mine sent 11 cars to Wisconsin Zinc Co. separators, 430 tons. Oliver Mining Co. is making ore and has covered its initial consignment.

Dodgeville.

This district, little heard from recently, has several fairly good zinc mines but operators were holding for better prices and shipments for week ending Nov. 11; included 7 cars from the Lucky Five Mining Co., 275 tons, and 3 cars from the Carl Guthrie Mining Co., 106 tons, all to the Eagle-Picher Lead Co. Other producers continue to hold and about 300 tons more remain ready for shipment.

Cuba City.

National Separators Co. received 54 cars crude ore in the past 2 weeks. Shipments for week of Nov. 11, of high-grade refinery ore were made to Illinois Zinc Co., 6 cars, 224 tons; American Zinc Co., 5 cars, 217 tons. The latter is now more active on buying and is cutting in appreciably on other large buying firms. Linden Zinc Co., operating a refinery here as well as at Linden, shipped 1 car high-grade, 40 tons.

Hazel Green.

The regular shippers, Kennedy, Cleveland and Lawrence mines, gave their weekly accounting for Nov. 11; 8 cars, 310 tons. The Monmouth Zinc Mining Co., one of the new projects of the year with full equipment, suspended operations and is giving attention to more thorough exploration of the leasehold. The McMillan Zinc Co., with new equipment, extensive exploration work, etc., has so far failed to report shipment of zinc ore.

Benton.

Two new producers have been ushered into active co-operation with regular performers, one for the Wisconsin Zinc Co. on the Longhorn farm which began trial run on

Nov. 15. The plant will be able to handle 400 tons daily and will have an auxiliary mine to draw from on the Murphy land adjoining where a new shaft is in ore and is now being equipped with necessary machinery. A surface tram is being laid between this new producer and the main Longhorn.

Reports handed in for week of Nov. 11 showed shipments of 55 cars of zinc concentrate, 4,344,000 lbs.

Another new producer is now producing on the Grotkin land for J. H. Billingsley, et al; the mill houses a 9 cell jig. The new plant is known as Mill No. 2; and provides an outlet for a large run of ore found just under the flint and 80 ft. above the oil rock, where the Grotkin range is exceptionally strong. Should this top run not prove as profitable as now calculated the shaft will be dropped down 80 ft., picking up the oil rock range.

Potosi.

A. B. Patterson, Supt. of the Tiffany Zinc Co., successors to Tiffany Mining Syndicate, and in charge as General Manager for the Chicago Zinc Co., reports the new 500-ton power and concentrating plant nearing completion and scheduled to make its trial run the first week in December. A rich strike of lead ore on the Horse-Shoe property is one of Patterson's latest finds. The land is being explored with drills at the same time the mine is being opened up. Shipments of high-grade wet concentrates came from the Wilson mine last week, 1 car to LaSalle, 44 tons, and 1 car to Grasselli Chemical Co., 42 tons. All zinc ore deposits found in this section of the Mississippi River valley are practically free of marcasite and a high-grade concentrate is made obviating the necessity of magnetic separator treatment entirely.

CANADA.

BRITISH COLUMBIA.

Silverton.

Two feet of clean galena ore has been opened in the lower tunnel of the Echo mine, which adjoins the Alpha claims of the Standard mine, according to L. J. McAtee of Spokane, who is associated with John Jordan in the operation of the property. Drifts have proved the shoot for about 40 ft., and preparations are being made for crosscutting and raising. The tunnel is in about 700 ft., and gives a depth of 700 ft. The lower tunnel on the Echo is No. 1 tunnel of the Alpha, and was run to the Alpha lines by the Standard people, who found ore. The Standard, McAtee said, is now stopping from a 16-ft. shoot of clean ore which is said to run around 200 ozs. silver. Both the Echo and Alpha properties are in the same big ore zone in which the Standard has found its big shoots. Arrangements are being completed for the winter's work, and it has been decided to increase the force of men employed to 10. Work at the Echo is facilitated by the courtesy of the Standard people, whose tramway runs within 1500 ft. of the operations on the property.

Recent reports state that 3 ft. of clean lead ore has been encountered in the No. 5 tunnel of the Standard mine. This is the third important strike in the property in the last few weeks, two exposures of high-grade lead-silver ore having been made in the upper tunnels of the Alpha claim in September, and these now are being drifted on. A winze now is being sunk on the galena shoot struck a number of months ago in the No. 7 level, and which has been extensively developed on the discovery level.

Both the new tunnels in the upper portion of the Alpha claim of the Standard Silver-Lead Mining Co.'s group continue to show solid galena ore from 3 to 4 ft. wide, according to Charles Hussey, secretary-treasurer. They are on levels only about 40 ft. apart, and the ore body is so twisted that until the workings have been connected up it is impossible to estimate the probable tonnage of ore they will yield. Every one who has inspected the showings is confident that they constitute the apex of another bonanza ore body and the management is now laying out development work which will disclose the extent and trend of the ore shoot. Besides the clean galena, which is unusually high in silver as well as lead, there is a considerable body of fine concentrating ore

disclosed in the new workings. On the No. 7 tunnel level, which has long been in a body of zinc ore, a crosscut was recently driven to the north 100 ft., resulting in the disclosure of a parallel vein which is now believed to be the ledge in which the main workings of the mine are situated. An up-raise in the new vein has opened a stringer of clean galena on the hanging wall which is identical in character with the ore heretofore produced from the bonanza ore shoot. Near the mouth of the No. 7 tunnel is a body of clean galena about 100 ft. long and 3 ft. wide to which no attention has been devoted beyond stoping out the ore which occurred above the tunnel level. A winze is now being sunk on this ore. The company is consequently developing shoots of clean ore in the two extremes of its ground, at the same time that its workings in the No. 7 tunnel are either opening up a new ledge or are for the first time exploring on that level the ledge from which all the mine's production to date has come.

A winze is being sunk in the No. 7 level of the Standard on clean galena which was recently encountered. The new ore body in the Alpha claim is maintaining itself under development and a new find of 3 ft. of clean lead ore has been made in No. 5 tunnel.

Ferguson.

At the Triune mines in No. 3 tunnel, 400 ft. from the portal, a crosscut was made and a new vein of high-grade struck. The ore assays 300 ozs. silver, besides gold and lead values. The lead gives a stoping ground of over 300 ft., and will be caught again by No. 4 tunnel, which is now in 600 ft. It is estimated 50 ft. further in No. 4 will strike the new vein. Next season is expected to see the Triune a steady shipper. Next year Manager Battey hopes to be able to put in an aerial tram from the mine down Triune creek to the wagon road at Eleven-Mile and from there deliver it by auto trucks to the head of navigation.

Rambler-Cariboo recently received a check for \$4587 for a shipment of ore running 101.7 ozs. silver and 46.6% lead. In addition to the payment just received, the company received a check recently for \$14,260 in payment for 513 tons of zinc concentrates shipped to the Kusa Smelter Co. in April. The gross value was \$21,197, the freight \$5431, and the duty \$1504. The company has a further asset in its possession of 1000 tons in the zinc stockpile, valued at \$28,000 net, to which a production of \$2000 a month may be added. A sale of the zinc will be negotiated by A. F. McClaine, president, while in the east this month. The zinc content of the spring shipment was 33.09% and silver 28.43 ozs. The duty was \$2.80 and freight \$10.10 per ton.

Sudbury.

The International Nickel Co. produced in August 7,600,000 lbs. of nickel. This is a great increase over any previous month. During the year ending June 30, 1916, Canada exported to the United States 52,742 tons nickel-copper matte containing 64,622,286 lbs. nickel, and worth about \$16,000,000. During the same period Canada exported a large quantity of nickel-copper matte to Wales. The nickel contents of matte shipped to both countries will total about 76,000,000 lbs., worth about \$19,000,000. In other words, there was shipped during the year ended June 30, 1916, from the smelters in Ontario, matte worth about \$24,000,008. The metals in the matte when refined would be worth about \$40,000,000.

Vancouver.

The Coast Copper Co., capitalized for 1,000,000 shares at \$1 each, has been organized in British Columbia, and the headquarters of the corporation will be at Trail. The stated purpose of the company is to acquire from M. W. Bacon and W. E. Cullen of Spokane by purchase, 31 mineral claims and an option on 14 others, together with the equipment already installed, in the Quatsino district, Vancouver island. Reports received from Nelson state that the Coast Copper Co. is a subsidiary of the Consolidated Mining & Smelting Co. of Canada, and that the holdings mentioned are those of the Quatsino Copper Co., in which other Spokane men than Bacon and Cullen are extensively interested. If this report is correct, and there is every reason to believe that it is, it means that important development is assured for the Quatsino district, as the Consolidated has the capital and the talent to bring into production the immense copper deposits in that

field. The Quatsino holdings at one time were under option to the Stewart Mining Co., but, following an adverse report from an engineer the option was allowed to lapse. During the life of the option considerable development was done, and it is said that immense bodies of low-grade copper ore were proven. No deep development was done, however, and the belief prevails that only work at depth will reveal ore bodies worth while for operations on an extensive scale. It is said that in recent months engineers representing the Consolidated have made exhaustive examinations of the groups, and that their reports were satisfactory. The Quatsino holdings are several miles inland from June Landing on Quatsino Sound, but a railway line has been surveyed from tidewater to the mine workings, and there is no doubt but that this line will be constructed if the Consolidated makes the purchase. Nearly the entire distance will be heavy construction, owing to the mountainous nature of the region, but there are no particularly difficult engineering problems to solve. June Bay is an excellent harbor, and deep-sea vessels can easily berth at the landing, a condition that assures cheap transportation to the smelters for the output of the property.

ONTARIO.

Cobalt.

As a result of favorable returns from a recent thorough sampling the Little Nipissing is to be worked by Detroit and Toronto interests which have a lease on it. The workings are connected with those of Peterson Lake and Seneca on the 155 level. When this level was reached through the 325-ft. Little Nipissing shaft considerable water came in from the other properties. A concrete bulkhead was put in so that now one pump working 3 hrs. a day can handle the water. Pumping has been resumed and the shaft will be unwatered a few feet further. On the 100 and 155 levels some high-grade has been found in three veins in the old workings, also a considerable amount of low-grade in the old stope at the 100 level. It is understood that operations will be under way on a large scale in the very near future.

Port Colborne.

The Foundation Co. Ltd., Montreal, is to start work at once on the refinery which the International Nickel Co. is to put up near here. It will cost about \$5,000,000. The plant is being erected ½ mile southeast of the lake city. Eight hundred men will be put to work immediately to rush the reinforced concrete foundations to completion before snow comes. Work, however, will be continued through the winter.

Kirkland Lake.

Labelle-Kirkland intends further development and sinking of its shaft which is now down 275 ft. At the present level the ore body is a good milling grade. A contract for 5000 ft. of diamond drilling has been let for the purpose of ascertaining the extent of the bodies at lower levels, so that plans for the mill, which will probably be installed within the next few months, can be arranged for. It is the intention of the management to put in a mill that will not have to undergo any material changes owing to the volume or the nature of the ore. The property is under the management of Frank C. Loring.

Porcupine.

The installation of a new compressor is now under way at the West Dome Con. and a new shaft will be started immediately 1500 ft. west of the old shaft. About 250 ft. of lateral work has been done at the 300-ft. level. Both east and west drifts are in ore which it is estimated will average \$10. The vein is about 7 ft. wide. In a crosscut on the same level the vein is 5 ft. wide and the ore runs from about \$2.50 to \$10.

Timmins.

The ore treated during September at the Porcupine Crown was considerably higher than during previous months. A lot of ore from the section of the vein lately opened up at one of the lower levels ran very high. Development work is confined to sinking the winze now at the 880 level. It was intended, for a time, to cease sinking and run drifts at the 800. Diamond drilling was resumed at the end of September. Because not enough air could be provided to carry on both operations, development in various levels was stopped.

World's Index of Current Literature

A Weekly Classified Index to Current Periodical and other Literature, Appearing the World Over Relative to Mining, Mining Engineering, Metallurgy and Related Industries, in Four Parts.

Part 1. *Geology*—(a) Geology; (b) Ore Genesis; (c) Mineralogy.

Part 2. *Ores and Metals*—(a) Metals and Metal Ores; (b) Non-Metals.

Part 3. *Technology*—(a) Mines and Mining; (b) Mill and Milling; (c) Chemistry and Assaying; (d) Metallurgy; (e) Power and Machinery.

Part 4. *General Miscellany* (including Testing, Metallography, Waste, Law, Legislation, Taxation, Conservation, Government Ownership, History, Mining Schools and Societies, Financial, etc.

Articles mentioned will be supplied to subscribers of *Mining and Engineering World* and others at the prices quoted. Two-cent stamps will be received for amounts under

\$1. Subscribers will be allowed a discount of 5 cts. if the price of the article exceeds 50 cts. The entries show:

(1) The author of the article.

(2) A dash if the name is not apparent.

(3) The title, in italics, of the article or book. Titles in foreign languages are ordinarily followed by a translation or explanation in English.

(4) When the original title is insufficient a brief amplification is added. This addition is in brackets.

(5) The journal in which the article appeared; also the date of issue, and the page on which the article begins.

(6) Number of pages. Illustrated articles are indicated by an asterisk (*).

(7) The price.

November.....	51.713	24.640
December.....	55.038	26.232
Year.....	49.690	23.470

Difference in domestic and foreign prices explained by the fact that the New York quotations are per fine ounce; the London per standard ounce 8.925 fine.

Copper.—Business in copper last week was in itself tremendous. Orders for 350,000,000 lbs. were taken. One purchase involving 100,000,000 lbs. for delivery in the first quarter of next year started the market on a sharp upward reach to higher prices. The French inquiry will become active very shortly. As yet producers have not been definitely approached, although they have been informed of the fact that such an inquiry is in the market. When England bought 448,000,000 lbs. only a month ago the trade thought that foreign buying was completed for some time to come. The decision of the French government to buy 225,000,000 lbs. at this time is likely to influence England to do the same thing. Therefore the copper market instead of merely enjoying a temporary demand for second half business is likely to experience a tremendous absorption of the red metal. Some important producers assert that very heavy selling for the second half is in prospect. One authority predicted that before the movement came to a close the producers will have written orders for at least 75% of their second half output into their books.

Prices are extremely difficult to quote. All copper for delivery prior to June is subject to negotiations. Sellers will not give quotations except on firm inquiries. While spot sold at 32 $\frac{1}{4}$ cts., it is stated that business at 35 cts. could now be done. Casting copper has sold freely for the first quarter at 29 cts. Sellers of lake copper have also obtained a very large business at prices ranging from 30 to 31 cts.

Acting under the influence of the strong cables from this side, the London market has advanced electrolytic going up to £152 for spot. Standard copper has advanced to £128 10s for spot and £123 10s for futures.

Quotations for copper per pound at New York for the week ended Nov. 15 were as follows:

(For first quarter delivery.)

	Lake.	Electrolytic.	Casting.
Nov. 9.....	29 $\frac{1}{2}$ @30	29 $\frac{1}{2}$ @30	27 $\frac{3}{4}$ @28 $\frac{1}{2}$
10.....	30 @30 $\frac{1}{2}$	30 @30 $\frac{1}{2}$	28 @28 $\frac{3}{4}$
11.....	30 $\frac{1}{2}$ @31	30 $\frac{1}{2}$ @31	29 @29 $\frac{1}{2}$
13.....	30 $\frac{3}{4}$ @31 $\frac{1}{2}$	30 $\frac{3}{4}$ @31 $\frac{1}{2}$	29 @29 $\frac{1}{2}$
14.....	31 @.....	31 @.....	29 $\frac{1}{2}$ @30
15.....	31 @.....	31 @.....	29 $\frac{1}{2}$ @30

Quotations for copper per ton at London for the week ended Nov. 15 were as follows:

	Standard		Electrolytic.
	Spot.	Futures.	
Nov. 9.....	£124 10s	£120 10s	£148

Tin.—Small arrivals and difficulty in obtaining export permits from the English government have acted to send tin to higher levels. Spot straits has sold up to 43 $\frac{3}{4}$ cts., with spot Banka selling at 42 $\frac{3}{4}$ to 43 cts. The spot position is very strong. Although the statistics showed a large stock on hand on the first of the month, it is ascertained that the bulk of this tin in store is for the account of leading consumers. There was a fair demand for January, February and March arrivals, but sellers could not offer, as London cables told of the difficulty in securing permission to make shipments. Some of the tin on the Glenlogan was for American account. Banka tin ex steamer Rotti due in January sold at 41 $\frac{1}{4}$ cts. London offered December arrival at 42 $\frac{1}{4}$ cts. and the trade quickly took up these offers, the price later advancing to 43 $\frac{1}{2}$ cts. Limits from the east for April, May and June shipments ranged from 41 $\frac{1}{4}$ to 42 $\frac{1}{4}$ cts., but con-

sumers were mainly interested in nearer shipments. Arrivals of tin since the first of the month total only 500 tons. The stock afloat to this country totals 4202 tons, of which 2952 tons are on unflamed steamers, so that the outlook for November imports is not very good. Last week straits tin at London advanced £2 5s to £185, with further advances this week.

Quotations for tin per pound at New York and per ton at London and Singapore for the week ended Nov. 15 were as follows:

	New York		London,	Singapore

Lead.—Demand for lead has failed to show any improvement since our last report. Producers attribute the inactivity to an effort on the part of certain large consumers to test the strength of the market. As yet no seller has offered at concessions. With all of the producers sold out for November delivery and holding good orders against their December output, it is not likely that there will be a weakening in the situation. Producers are waiting for a renewal of demand and in the meantime are quoting 7 to 7.05 cts. New York for December delivery. It is suggested in certain quarters that these quotations will not prevail very long after buying is resumed. Dealers did a small business in spot metal. Generally, however, the market has been extremely quiet. At London the market fails to show any sign of life. London advices do not throw much light on the inactivity. Since Oct. 13 the London market for lead has remained at £30 20s for spot and £20 10s for futures. Information as to what the A. S. & R. Co. contemplates along the line of price changes appears to indicate that the prevailing figures of 7 cts. New York and 6.92½ cts. St. Louis will be continued.

Quotations for lead per pound at New York and per ton at London for the week ended Nov. 15 were as follows:

Lead Ore.—Strength was the predominating feature in the ore markets of the Missouri-Kansas-Oklahoma district during the week ended Nov. 11, but even for this prices of lead ore remained at from \$83 to \$87 as during the previous week. Sales during the week amounted to \$45,353 from 1,223,820 lbs. of concentrates. This brought the total for the year to date at 88,746,702 lbs., valued at \$3,674,610 lbs.

Zinc Ore.—Zinc ores in the district partook of the prevailing strength and prices jumped \$10, bringing the top price up to \$90 per ton and the lower grades at \$75. Sales of 15,328,532 lbs. of concentrates during the week amounted to \$632,720. Ores produced and sold during the year to date amounted to 607,296,772 lbs., valued at \$24,178,783.

Calamine.—Prices of this ore were also up and ranged from \$45 to \$50. There were 1,664,020 lbs. of concentrates sold during the week and this amount was valued at \$39,895. The total for the year to that date was 32,953,605 lbs., valued at \$970,322.

Spelter.—A very large business has been done in spelter for delivery over the first quarter of next year and a fair amount of selling has also been done for delivery in the second quarter. Domestic consumers were steady, but latterly export buyers came into the market and took considerable amounts for delivery over the entire first half of next year. As a result spelter prices have advanced. With first quarter delivery of prime western selling at 11 cts., producers have become sellers. Hitherto producers limited selling, but with buyers willing to pay 11 cts. they have started to take orders. Galvanizers were the principal buyers, but brass makers have also been in the market. Spot prime western has advanced to 11.50 cts. New York and 11¼ cts. St. Louis. Since our last report business for the first quarter has been done at prices ranging from 10¼ cts. up to 11 cts., with the outside price now prevailing. The sharp advances in zinc ores are in a measure responsible for the active demand for spelter, but consumers were not covered at all for the first quarter and the reasonably low prices that were available a fortnight ago were also factors. Brass special has held steady at 11 cts. St. Louis for spot. Zinc sheets were advanced to 17 cts. base. At London spelter has advanced, going up £2 5s in spot and £1 15s in futures last week, with further gains this week.

MISCELLANEOUS METALS.

Antimony.—Continued inactivity has resulted in first hands shading prices on spot and forward metal. Spot antimony has been offered at 13 cts. duty paid and some sellers indicate that they would accept a shade under this price. November and December shipments are being offered at 11¼ to 11½ cts. in bond. It must be borne in mind that leading antimony producers are still filling contracts that were made around 30 to 35 cts. and, therefore, they are in a position to disregard the spot market. Other producers, however, are not so fortunate and the low prices are beginning to result in the closing of plants. Needle antimony holds at 11 to 11½ cts. A fair demand for antimony ore is reported, with the market steady at \$1.60.

Molybdenite.—Sellers report a good demand for prompt molybdenite, but the supply is very small and business is restricted. Prompt is quoted at \$1.70 to \$1.80 per lb. for MoS₂. There has been a good business done in ferromolybdenite at \$4 for prompt and \$3.65 for forward contracts.

Quicksilver.—Business continues of fair volume, with the market steady and unchanged at \$80 per flask. There are numerous reports of an early advance in price, based on difficulty in obtaining supplies, but leading sellers assert that the market will continue on its present basis for some time to come.

Sheet Zinc.—The price of sheet zinc has been advanced 1 ct. to 17 cts. base as a result of the upward movement in the primary market.

Copper Wire.—Wire drawers are quoting a wide range of prices. Some makers are quoting 32½ cts., while others report sales at 34 cts.

Tungsten.—Demand continues quite active for spot and forward tungsten, but sellers report that future business is difficult to close. Spot business has again been done at \$17 to \$18 per unit, the price depending on grade. Arrivals are being easily absorbed, sellers reporting that only a small quantity remains on the market. Ferro tungsten continues at \$2.60 per lb.

Pig Iron.—Sensational price advances continue in pig iron. At Buffalo high silicon irons have sold at \$28 furnace. At Pittsburgh Bessemer has sold at \$27.50 and basic at \$24. Ohio furnaces have done business at \$25 and Chicago furnaces at \$26. Foundry and malleable grades have sold in the valleys at \$24.50 to \$25. At Birmingham the situation is very strong, with No. 2 iron selling at \$20.50.

Coke.—The situation in coke is alarming. Spot foundry coke has sold at \$11 a ton ovens. Spot furnace fuel has sold at \$7 ovens. Coke producers report a very active demand for 1917 contracts from blast furnace interests.

No. 22. Vol. 45.

CHICAGO

November 25, 1916.

Nineteenth Annual Meeting American Mining Congress

The American Mining Congress held its 19th annual meeting in Chicago last week. Much interest was manifested in the various sectional gatherings and many of the topics discussed were exceptionally interesting; however more to the scientific rather than to the practical end of the industry.

Mining has a bearing on all the industrial activity of mankind. Modern industry, including practically all our manufacturing and construction industries, railroads and transportation, represents largely the working and reworking of the substances to which mining has given birth. Our buildings, our structural materials, our metals, our utensils and machinery, our inorganic chemicals—all these things the world owes in the first instance to the mining industry.

In the United States in the year 1915 it is estimated there was employed in the mines and quarries no less than 1,750,000 men, 1,000,000 being employed in the metal and non-metal mines. On the mine owners, operators and investors who are responsible for the means of livelihood of so vast a number, who alone supply industry and commerce with all their coal, oil and metals, stone, cement and clays, etc., there rests a great responsibility that has been well borne.

General Session.

Monday, Nov. 13, 1916, 2:30 p. m.

The meeting was called to order at 2:30 p. m. by Harry C. Adams, chairman committee of arrangements and chairman of the executive committee.

Harry Atwood, attorney for the Board of Local Improvements of the city of Chicago, representing Mayor William Hale Thompson, greeted the Congress with an appropriate welcome.

J. W. O'Leary, on behalf of the commercial interests, in welcoming the Congress to Chicago stated that Chicago consumes something like 25,000,000 tons of coal and in it manufactures tons and tons of metals. Illinois, as you know, produces something like 60,000,000 tons of coal a year. He added:

Yours is rather a wonderful industry. Your product began forming before history began. It is the greatest commercial necessity, including the metals, the greatest commercial necessity of today. It is absolutely essential to our industrial progress and Chicago particularly is under obligations to you for what your mines have produced, for we are, a manufacturing and industrial center fundamentally. That is the basis of Chicago's greatness today.

We are rather proud of Chicago. Some folks say we boast of it. I prefer to say that we boast it. We are rather proud of our parks and our boulevards and we invite your attention to

our development of the small park idea. We think we are leaders in it. You will enjoy it. We are rather proud of our art institutions, our educational institutions. You may have noted through the papers within the last few days that Chicago is to be the medical center of the United States, and we hope with the co-operation of the rest of our nation, of the world. We are rather proud of our commercial establishments, our manufacturing establishments; and I am sure that you will find it well worth your while to visit our great manufacturing institutions. You will find that the open door policy prevails towards such men as you. We are proud of our mercantile establishments. You will find them ready to receive you, whether you spend money or not.

Chairman Adams said:

The year closing in the metal and mining business has been a remarkable year in many respects. It has been a very prosperous year in a great many of the metal industries. We have had a good deal of bad and a good deal of good business in the coal business. We do not know how long the good business is going to last in the coal business. Usually it does not last very long. The attention of this Congress, in my judgment, should be given largely or at least a large part of it should be given and consideration should be given to the standardization of cost accounting, both as to minerals and to the coal mining. After we pass through the abnormal conditions that are surrounding us now we certainly will be in bad shape, so far as marketing coal is concerned, or marketing metals is concerned, unless we know, all of us, what our product is going to cost and what it does cost.

The program as outlined here is a pretty long one. It is going to take lots of work to get through. Your committees have made some efforts along the lines of entertainment and we hope that you will have a pleasant time and a profitable time while you stay in Chicago.

I think the Association is fortunate in having the guidance of such an expert mining man as Carl Scholz, the president, to whom I now turn over the convention.

Short responses were made by delegates from the various states represented, including Arizona, California, Colorado, Idaho, Indiana, Illinois, Iowa, Minnesota, Missouri, Montana, Kansas, Kentucky, North Dakota, Pennsylvania, South Dakota, Tennessee, Utah, Virginia, Washington, West Virginia and Wisconsin.

Tuesday, Nov. 14, 1916, 10 a. m.

At this meeting it was announced by Secretary Callbreath a memorial volume to the late Dr. Joseph A. Holmes had been printed.

The selection of a committee on resolutions, owing to a misunderstanding, was deferred to a later session.

It was announced by the secretary that the proceedings of the Congress will be sent to all members without additional charge. Non-members will be supplied at a cost of \$1.

At this session Hon. Edward N. Hurley, chairman of the Federal Trade Commission, read a paper on the relation of the Commission to the mining industry.

Albert H. Fay, of the United States Bureau of Mines, outlined the work and gave a summary of the records of the mine safety work conducted by the U. S. Bureau of Mines. Mr. Fay said in part:

The United States occupies the unique position of producing more coal than any other country in the world, uses more mining machines and produces a larger percentage of coal by mining machines than any other country. It produces more coal per man employed than does any other country and also produces more coal per fatality than any other country. But, unfortunately, we produce more fatalities per thousand men employed than does any other country, except possibly British Columbia, which is not much larger than one of our own states

In 1870 Pennsylvania introduced mine inspection in the anthracite field. The production of coal that year in the anthra-

site field represented 47% of the coal produced in the United States. Therefore, in 1870 we have 47% of the coal produced under mine inspection. In the next year, 1871, we only had about 44%. In 1875 one or two other states had come in with inspections and we had about 52 or 53% under inspection, and so on year by year until in 1880 we have 75% under inspection. The percentage increases up to 1895, when we have about 99% under inspection. Other states have come in until at last there is less than one-tenth of 1% of coal that is produced without any inspection service whatever.

Thus is shown the growth of inspection service in reference to the production of coal in a period of forty-odd years. In 1870 the fatalities per million tons of coal mined were 13. In 1875 the fatalities per million tons of coal mined were about 9. In 1880 it was a little above 5. Since that period it has remained around 5 per 1,000,000 tons until in 1907 it was almost 7. From 1907 the rate has declined very noticeably until in 1909 we produced 234,000 tons for each fatality.

Now, based on the number of men employed, in 1870 we had six men killed per thousand men employed. The inspection service has grown and the rates have declined until for a long period of years it remained in the neighborhood of 3 per 1,000 men employed. Beginning with about 1895 the rate has gradually increased year by year, until it culminated in 1907 with a fatality rate of 4.81 per thousand. From 1907 that rate showed a decrease, also a decrease in the number of men employed.

In his paper on "State Mining Rescue Stations," Prof. H. H. Stoeck, of the University of Illinois, reviewed the work carried on in the state of Illinois, saying in part:

In 1909 the Technologic Branch of the United States Geological Survey, now the United States Bureau of Mines, in co-operation with the Illinois Geological Survey and the College of Engineering of the University of Illinois, established at the University of Illinois in Urbana, a rescue station for the training of miners and mining officials in the Middle West coal fields.

One of the results of the Cherry disaster was a strong demand for greater safety measures in the state and during the winter of 1910, the State Legislature upon the suggestion of the Illinois Mining Investigation Commission, not only added a number of safety provisions to the state law, but also appropriated \$75,000, for the erection, equipment and maintenance of three rescue stations, placing the administration of the stations in the hands of the Illinois Mine Rescue Station Commission, consisting of seven members, including two coal mine operators, two coal miners, one state mine inspector, one representative of the Department of Mining Engineering of the University of Illinois, and one representative of the Federal Bureau of Mines. The stations are located at LaSalle for the northern part of the state, at Springfield for the central part and at Benton for the southern section. The work of the Commission is at present being carried on in the following manner:

At each state station there is maintained in addition to the two permanent employes, a team of five men who train twice a week at the rescue station and are paid for their time. These men work in nearby mines and can be quickly assembled at the stations if needed.

Three sub-stations have been established in districts where there is the most called-for assistance and insofar as funds will permit and the demands of such stations seem justified, it is planned to establish other sub-stations. One or two permanent employes are in charge of each sub-station and at each sub-station there is maintained in addition a team of five men under the same conditions as the regular paid teams at the main stations. These stations are at present located at Herrin, Harrisburg, and Duquoin.

First aid classes have been organized in towns so near the main stations that the superintendent or assistant can reach such towns though living at the main station.

In addition to training men about the mines, a number of first aid classes have been formed in the public schools and in connection with various associations of men and women in mining towns. City firemen have also been trained and it is the policy of the Commission to encourage such training of persons not connected with the mines as much as possible if it does not interfere with the regular training of mine employes. The rescue men have also assisted the city firemen in fighting fires where it was impossible to enter a burning building without the use of breathing apparatus.

In a discussion of the "Responsibilities and Duties in Mine Safety Work," as devolving upon the operator, the miner and the public, Thomas M. Gann, Knoxville, Tenn., spoke for the operators, whose responsibilities he claimed were if possible greater than the others. In his opinion cheap coal is the principal cause for the awful destruction of life incident to the development of the industry.

At this part of the program the members and guests were asked to rise as a mark of respect to the late David Ross, of Springfield, who passed away since the program was made up. Mr. Ross was to have discussed "Mine Safety Work" from the standpoint of the miner.

Thos. L. Lewis, of West Virginia, discussed the question from the point of the miner, calling attention to the fact that the danger surrounding the work of the miner can be classified into two classes—the unknown, the generation of any quantity of fire damp and the known dangers, such as undermining under the old pick system.

Dr. F. W. McNair, president of the Michigan School of Mines, was called on to represent the public in the discussion. He was of the opinion that the most effective way in which the public can influence the mine operator and the miner was through the workmen's compensation law. It was through this that the mine operators and miners were influenced in

the matter of safety-first. He did not, however, feel like holding the public responsible for any very direct result until the facts can be put to them much more efficiently than they have been in the past.

Committee on Resolutions.—The following committee on resolutions was selected by the various state delegations:

Alabama—W. E. Henley.	Montana—James Needham.
Alaska—B. F. Allard.	Nevada—A. A. Codd.
Arizona—J. H. Robinson.	New Mexico—T. H. O'Brien.
Arkansas—Ransome Gulley.	New York—Chrissy Morrison.
California—Jas. M. Gillette.	North Carolina—H. R. Smith.
Colorado—Geo. E. Collins.	Ohio—W. R. Woodford.
Dist. of Col.—Van H. Manning.	Oregon—F. Wallace White.
Idaho—Eugene Thomas.	Pennsylvania—E. W. Parker.
Indiana—W. S. Bogle.	South Carolina—Mr. Chambers.
Illinois—F. C. Honnold.	South Dakota—M. S. Brede.
Iowa—Joshua Norwood.	Tennessee—A. H. Purdue.
Kansas—Mr. Skidmore.	Utah—Mark P. Braffet.
Kentucky—F. P. Wyatt.	Virginia—J. S. Grasty.
Michigan—F. W. McNair.	West Virginia—D. C. Kennedy.
Minnesota—J. E. Hodge.	Washington—Sydney Norman.
Missouri—W. B. Shackelford.	

Wednesday, Nov. 15, 1916, 10:00 a. m.

Dr. James E. Talmage, of Salt Lake City, Utah, presided as chairman, and called the meeting to order.

Dr. David T. Day, chairman of the Joseph A. Holmes Memorial Committee and also secretary of the Joseph A. Holmes Safety Association, reported on the work of that committee as follows:

At the meeting of this Congress a year ago you appointed a committee which conferred with a similar committee of the American Institute of Mining Engineers to organize a suitable memorial for Dr. Joseph A. Holmes, first director of the Bureau of Mines.

The two committees agreed that the most suitable memorial would consist in perpetuating Dr. Holmes' work of benefiting mining, an organization having such a purpose, and we found all the national societies glad to join in a national safety movement. The year has been spent in bringing them into an organization. They are now joined in the Joseph A. Holmes Safety Association.

In the Nov. 4 issue of Mining and Engineering World you will find Dr. Holmes' own recognition of what the Bureau of Mines owes to the Mining Congress in the organization of that bureau: "This movement for appropriate recognition and aid for the mining industry from the national government has been under way for many years. Among its early and most active supporters have been the California Miners' Association and the American Mining Congress. It is, therefore, eminently appropriate that at the first session of the American Mining Congress, following the creation of the Bureau of Mines, at a session held in California, something should be said of the policy and purposes of the new bureau."

And I believe that the American Mining Congress by the way that it stood for federal recognition of mining from the beginning of the Congress really is more the father of the Bureau of Mines than any other organization in the United States and can point to that magnificent bureau as more its child than that of any other organization.

We found that all national societies were glad to come into a co-operative movement which would benefit mining in the same way that Dr. Holmes had undertaken to make that his life work. That was a very gratifying thing. We got representatives of these societies together, altogether 22 of them. It was easy to form an organization of this character. It was particularly fortunate that the members to represent the representatives of these different national societies were chosen with a great deal of care, forming a magnificent body as the foundation of this organization. From that body they chose as officers the director of the Bureau of Mines as president and thereby secured at once the co-operation of that great Bureau in our work, and also made it easy to avoid any duplication of work which could be carried out through the instrumentality of the Bureau of Mines. As vice-presidents they chose Dr. Charles D. Walcott, the former director of the U. S. Geological Survey, and now the secretary of the Smithsonian Institution; and Mr. Gompers, president of the American Federation of Labor. Thereby, we laid the possibility at once for such co-operation in this work with labor itself as would enable us to begin right at the bottom of the difficulties of safeguarding mining, that make the miner come into this thing in a way which would begin where we ought to. The miner's greatest enemy, as we all must admit, as the miner himself will admit, is the miner; and we have gone to these miners in a very practical way. The Federation of Labor is going to them and getting each miner in the country to contribute something toward the fund of this Association, a permanent fund, the interest from which is to carry on the work of the organization. Now, so soon as a miner has invested 50 cents or \$1 in something and has received a statement, a certificate of membership, he is not going to forget to inquire what became of that money and where he gets something back; and just as soon as he does that his education in safety in mining has been begun and we have a means of getting at that man to keep up his education. If this Association could succeed that way in simply making each miner a little safer to his fellow miner, then what a great step forward this national movement would have accomplished. And then when we think that by the appointment of this Committee last year this Association becomes the father of this new movement, you can recognize that only second to the formation of the Bureau of Mines itself is the initiative taken by this body in forming the Joseph A. Holmes Safety Association. We have here, in other words, an association by the name of which we honor Dr. Holmes, by the purposes of which we are going ahead to make mining safer.

How are we going to do it? That is a matter which is

shown very well in an announcement which all of you will receive, a copy of which I hold in my hand. It is an announcement of the membership, the officers and such purposes as have been decided upon at the present time as the work of this association. We propose to make mining safer by bestowing on any man or any number of men a prize for anything contributed in the way of safety in mining. I have an example in mind, without mentioning any names, of a man in Illinois, who was formerly a coal miner and has become the superintendent of a mine. That man posted a notice in letters about 6 in. in height, at the mouth of the mine, that a certain man had been injured. It stated the injury and it stated the way it happened. It stated then that the man would be compensated in due course, his illness would be taken care of, his family would be taken care of as best they could and the man would return to work in as well and as fit condition as they could make him; but nothing they could do would compensate him for the pain he had actually suffered, for the shock to his family and for the permanent loss of efficiency when he went back to work with one arm. That was all. There wasn't a word of moral. There wasn't any preaching. There wasn't any scolding. But that notice has been talked about by the miners on the street cars and elsewhere in that town more than anything else that has been posted of that sort for a long time. The idea of posting such a notice is to my notion; just as an individual of this Association, something well worthy of a prize as being a contribution to safety in mining. It does not mean that a man has to get up a new safety cage or some device for stopping a cage if it happens to get loose going down the shaft.

We propose also to give a medal to any man or any hundreds of men where one man contributes to the safety of another miner at the risk of his own safety, and we are giving that a definition of a hero for the purposes of this organization; and we believe that when such a man has received some recognition of that sort and his fellow-workers recognize it that we can also take that man, as has been suggested in California, where this Association was discussed a few days ago, we believe that we can take that man and send him around to his fellows in his own part of the country and by his own talks—we hope that he will not be a good lecturer; we believe that he will be just a plain talker, and heroes are not usually very much on talking—we believe by his own talks that he will further the movement of safety in mining. Now, we propose that that man shall spread the ideas of safety that he has received by a visit to us in Washington to receive this medal. In beginning that way we can really get at the miners themselves.

So far has the Association gone. This is no more than equivalent to the announcement which you will receive, and is the report of your committee at the present time, to which I wish to add this statement: The purposes as far as they have gone have been set forth. The further purposes, what shall be done by this Association, are in the hands of those who compose it, the members of the American Mining Congress, the Mining Engineers and the other composing bodies. We will carry out, and I believe these men who are certainly well chosen as national officers will carry out, the work that you entrust to them well.

To carry it out it must be supported. There must be a fund, and here is where we come to that question. What that fund shall be, how much it shall be, how little it shall be, is to be measured by your idea of what a national organization to represent the great mining interests of the United States shall have. You can make it large or small, according to what you think it should do. To do that, in the first place, our primary fund will be obtained by the personal contribution of the members of the American Institute of Mining Engineers, the members of the American Mining Congress and others, and there will come to you in due course a small blank with the announcement on it that we want your personal subscription for whatever you think you should give.

In his paper on "Federal Aid to Mining Efficiency," Van H. Manning compared the national importance of agriculture and mining and the aid rendered by the government. He finds that the government in the present year has donated to the farmers \$1 for every \$295 worth of the products of the farm. It has donated to mining \$1 for every \$1017 worth of products from the mines. "While the value of the agricultural production of the country is less than five times that of the mineral production, the per capita appropriation for agricultural investigations is 15 times the per capita." He said further:

No country in the world has such vast and varied mineral resources as the United States. The development of these industries has been rapid and on an enormous scale. In 1880 the value of the mineral products of this country, according to the Tenth Census, was \$264,000,000; in 1900 the value had risen to \$1,063,600,000; in 1910 to \$1,991,200,000, and in 1915 to \$2,373,000,000.

From 1880 to 1915 the population of the United States increased about 100 per cent, whereas the value of its mineral production increased nearly seven-fold.

But this tremendous increase in production has been accompanied by unparalleled waste, in both the production and utilization of our mineral wealth, and altogether too little regard for the health and safety of the men whose labor converted the natural resources into the commercial products. A people of restless energy, individualistic, eager for immediate success, and having little regard for the lessons of the past, we have indulged in an orgy of hasty exploitation, with the result that already we are nearing the limit of maximum production of some minerals, although the original supply, if wisely mined and utilized, would have lasted us many years longer and would have brought us ten times the wealth.

To conserve our remaining supplies, that is, to extract, prepare, and utilize the minerals and ores in such manner as will be of most benefit to the nation, is clearly not a simple nor an easy task. Our mineral resources are many and extend throughout great areas, occur under widely varying geological conditions, and are subject in large part to state laws that differ greatly.

In citing the needs of the mining industry Mr. Manning pointed out one in particular—the development of electro-metallurgical processes for the reduction of the base metals. In certain parts of the country, as the Pacific Northwest, vast water power, he stated, is available and electricity can be generated at a minimum cost. There a satisfactory electro-metallurgical process would make commercially profitable the working of millions of tons of mineral deposits that can not now be worked at a profit.

E. W. Parker, director of the Anthracite Bureau of Information, in his paper on "Co-operation, Conservation and Competition," claimed that it was encouraging to note that there is at last established under the Federal Government at Washington a tribunal whose words and deeds so far have shown that it realizes not only the desirability but the necessity for a higher degree of co-operation among the producers of coal, to the end that some stability may be given to the industry and we may hope before long to see coal mining given as fair a chance to exist under the Federal Trade Commission as railroading is under the Interstate Commerce Commission. He further claimed that:

It is reasonable to believe the time is not far distant when coal operators may and will co-operate in an exchange of information relating to trade conditions, car and labor supply, etc., so that production may be regulated somewhat in accordance with demand even as now the California fruit growers regulate their shipments with entire satisfaction to the consumers, and with a stabilizing of the industry from the growers' standpoint which was not dreamed of 20 years ago.

There is no branch of industry in which there is greater need of co-operation than among the retailers in any specialty—coal among the rest. Why should a coal dealer whose yard is in one part of a city deliver coal to a consumer two or three miles distant when another dealer could reach the same consumer by a haul of as many blocks? The coal merchants themselves are beginning to realize this, as is evinced by the discussions which constitute the larger part of the proceedings in their conventions. There is a disposition to get together and talk over matters affecting the economics of their business, to discuss candidly the problems that confront them, and to try by co-operative methods to improve their service to their patrons and incidentally to attempt to achieve a better return on their investment of capital, labor and brain.

The securing of a higher degree of co-operation between employer and employes, or between capital and labor, is perhaps a matter more difficult of accomplishment, but we can afford to be optimistic. If both sides contend honestly and strenuously for the strict observance of their agreements, each will have a higher respect for the other and be more willing to work in co-operation rather than in antagonism.

Much of our very best bituminous and semi-bituminous coals, as well as anthracite, have been lost through methods that must be deemed wasteful in the light of present knowledge, but which under the circumstances could not be avoided. It is not through reckless competition but through properly regulated co-operation that the highest possible recovery may be obtained, waste in mining, preparation, distribution, and utilization, reduced to a minimum, the public adequately served and protected, labor receive its just reward, and capital a fair return.

Competition, if it is to be the life of trade, must be competition that constructs and not that which destroys. Price cutting to secure an order and thus to injure the business of a competitor is not according to a high standard of business ethics. It is injurious to the trade as a whole. The rivalry among anthracite operators (for it is a rivalry) in the securing of better living conditions for their employes, to which I have already referred, is a competition of service. Its object, as I have stated, is through the improved living conditions to develop a better grade of workmen, who by rendering better service to their employers, will enable the latter to render better service to the public.

In his paper on "The Sherman Law and Its Relation to Mining," read by title only, Glenn W. Traer of Chicago defined the Clayton Act and the Trade Commission Act, the amendments to the Federal anti-trust laws of 1914, as being deficient in a practical understanding of the problems of industry or a spirit of helpfulness. He was of the opinion that they reflected a spirit of ossified suspicion, harshness and increased restraint.

Thursday, Nov. 16, 1916, 2:00 p. m.

S. A. Taylor, Pittsburgh, Pennsylvania, presided as chairman and called the meeting to order. The report of the Committee on Forest Relations, prepared by Carney Hartley, was read by title.

The committee devoted much time to the dissemination of information covering the rules for prospecting on forest reserves. Commenting on complaints the committee through its chairman, says:

From various conversations and other sources of information, it would appear that the intent of the Forestry Service is being very well carried out by the field officials. In some localities, at least, where there has been some complaint on this score, the difficulty has been that unfair advantage has been taken of the rules in various ways, compelling the For-

istry officials to exercise the letter of the law in order to carry out instructions. In some cases this has been due to a lack of appreciation of the spirit, in a few cases through an attempt to take unfair and unlawful advantage of the solution. It is generally believed, however, that by this time the situation is quite well understood and the principal need for the regulations is to show the prospector what his rights are under them, rather than to serve as information to cause friction.

Hon. Frank H. Short of California read a paper on "Conservation: Its Purpose, Its Effect, and Who Should Pay For It." He said, in part:

It is now about 20 years that I have been with considerable activity representing a good many men that have been endeavoring to develop the resources of the western states under the laws of the United States and the western states. And at times we have found that both difficult and troublesome and although we were engaged in doing nothing that wasn't being done in the open, although we were engaged in the construction of canals for the appropriation of water for the irrigation of land and reservoirs and canals and aqueducts for the development of hydro-electric power, and we were engaged in the development of mines and oil territories, I have frequently found myself in public gatherings placed in a position of wicked enemy of the people, desiring to do something wholly wrong, wholly undesirable and wholly inimicable to the public interests.

Now in mining out West, mining on the public lands, before much of the public lands of the West was disposed of it was provided by law that the mineral lands and latterly including the oil lands could not be disposed of except under the mineral law, and that meant upon the discovery and development of mineral justifying the patenting of the land by the government or the working of the land. So that while many of you people are from the East and you do not think of any land or title problems in connection with mining, that is about two-thirds of what the western miner has to think about, especially in recent years, or he finds himself in trouble.

As we first learned to understand the subject, conservation meant the saving and holding and better protection of the resources of the country and especially with respect to timber. And you know I never have seen a subject that divided itself as clearly as conservation does. Up to a certain point everybody agrees. We of the West have had no quarrel with conservation in the sense that it meant a better protection of the soil, of the timber, of the mineral resources of the country, and all of those resources, the conservation of water flow, and that sort of thing. We were always desirous of co-operating with it. But conservation grew and Jonah's gourd was not anything in comparison with what finally we were confronted with when we came to observe conservation in its final developments.

In concluding his paper Mr. Short said:

I want to say to you, gentlemen, that what I want to emphasize is this, that we people of the western states never come anywhere in the United States asking anything more than a square deal and absolute equalities. We talk about liberty and justice but without equality there can be no liberty, because if I am not equal with you I am not as free as you are. And without equality there can be no justice, because unequal justice is not justice at all. But we do believe that the western states and the pioneers who have settled them are entitled to be as free and as respected as those who developed the eastern and the central and the southern portions of this country. We believe that and we think you agree to it. The West was the left-over part of the country. Most of you, no doubt, have seen it, but for 30 years I have traveled on foot and on horseback through the mountains of that great region. I have seen its deserts and its fertile places and its great mountains. I wish that every man in America could get the spirit of the West in his veins, there, where real rivers find their sources in real mountains and flow through wide and fertile valleys into the world's most majestic sea. We want every American to view this from the equal standpoint, not of the West, not of the East, not of the South, but from the broad and equal rights of American citizenship, so that it does not make any difference what section of the country a man may live in but as an American citizen he has the same right to develop his home and enjoy the surrounding resources and live under the laws of his state as any other man in any other section of the American union.

A. H. Purdue, state geologist of Tennessee, read a paper defining the relationship between the state geologist and conservation. In the line of duties falling to the state geologist, according to Dr. Purdue, it is his duty to study and inform the public upon the occurrence, quality, quantity and uses of the natural resources of the state he serves. He divided his paper into four sections: The Inexhaustible Resources, the Exhaustible Resources, Soil and Timber Conservation, Legislation and Conservation and the Scientific Spirit. In conclusion he said that the state geologist should be a man who can make his work practical, but he should at the same time be a scientist with irresistible inclinations toward the purely scientific problems that confront him. Only such geologists, he said, can effectively serve a state.

Recently there has been impressed upon me the lesson that it is a duty of the state geologist to look carefully into developed mines, not only to ascertain if there is not a waste of the ore for which the mine is worked, or of some possible by-product, but of material that is too important to be classed as a by-product.

The object of most legislators in supporting geological surveys is to develop the natural resources; that is, to increase the wealth of the state. We have no fault to find with this attitude, and we willingly exert our energies to that end; but geological work, whether for economic or scientific purposes, requires the

strictly scientific spirit as its impelling force, without which no results can be relied upon.

The state geologist should be a man who can make his work practical, but he should at the same time be a scientist with irresistible inclinations towards the purely scientific problems that confront him. Only such a geologist can effectually serve a state.

Secretary Callbreath announced the election of the following members as directors to serve a term of three years: W. J. Richards, M. S. Kemmerer, George H. Crosby and W. J. Snyder. At the directors' meeting the following officers were elected: President, Walter Douglas; first vice-president, Charles M. Moderwell; second vice-president, George H. Crosby; third vice-president, L. A. Friedman; executive committee, Walter Douglas, Carl Scholz and C. M. Moderwell.

While waiting for a report of the committee on resolutions the subject of "Waste in the Mining Industry, in Mining, in Distribution and in Use—and the Relation of These Wastes to the Operators, the Consumer and the Public," was discussed. Among the speakers on this subject were S. A. Taylor, W. J. Snyder, and W. J. Kelley.

Resolutions Adopted.

The report of the Resolutions Committee was then taken up and the following resolutions adopted:

Federal Income Tax Law, Introduced by George E. Collins.

Whereas, The Federal Income Tax Law, as it applies to the output of mines, has been so construed by the Internal Revenue Department of the Federal Government as to work a grave injustice to operators, in that the deductions allowed from the gross income on account of depletion are not based on the gross value but on what is virtually the net value of the ore produced; and,

Whereas, Congress by a later amendment of the Act has shown its intention to permit more conservative deductions to be made on account of depletion of mines than was permitted under the law of 1913, now, therefore, be it

Resolved, That this Congress expresses appreciation of the intent of the Congress to be fair to the mining industry; and be it further

Resolved, That this question be referred to the regular Mining Taxation Committee of this Congress for investigation and recommendation; and be it further

Resolved, That such committee be instructed to take proper means to see that the construction placed upon this law by the Internal Revenue Department shall be in accordance with the plain intention of Congress in enacting the Act.

Mine Safety Work, Introduced by T. L. Lewis.

Whereas, In mine safety work, one of the most serious problems encountered, is the lack of personal co-operation on the part of some operators and also on the part of some miners, thus preventing the success of the work of promoting mine safety and reducing the number of accidents and fatalities in the mining industry; and

Whereas, While much has been accomplished, it is believed to be vastly important that every possible agency looking to greater safety in mining operations shall be enlisted and that efforts should be made to secure the active co-operation of those agencies which thus far have not voluntarily given their best support to the movement; now, therefore, be it

Resolved, That a standing committee of seven be appointed, which shall investigate this important subject and report its findings and recommendations to the next annual convention of the American Mining Congress.

Undeveloped Water Powers, Introduced by Frank H. Short, California.

Whereas, Conflict of laws and jurisdiction covering the development of water powers in the United States makes the use of vast undeveloped water power commercially difficult if not impossible, be it

Resolved, That it is the sense of the American Mining Congress in meeting assembled at Chicago, Illinois, November 18, 1916, that the Government of the United States of America and the several states be urged to enact such laws and regulations as shall facilitate to the greatest degree and safeguard the utilization of existing undeveloped water powers for industrial and domestic purposes, thus conserving and permitting the developing of our natural resources; and be it further

Resolved, That such laws should encourage and permit development of this resource and all of the other resources of the public land states without discrimination and under laws and conditions in all respects as favorable as those applicable in the states having no public lands; and be it further

Resolved, That copies of this resolution be transmitted to Congress, the legislatures of the states and the government and state departments having present jurisdiction.

Mining Laws, Introduced by J. N. Gillett.

Whereas, This Congress is deeply interested in the just operation of the mining laws, and

Whereas, As a result of certain land withdrawal orders by the President of the United States and of legislation by Congress many persons who at great expense and, as adjudged by the courts, have in good faith developed the oil lands of

the country are threatened with ejection and forfeiture of their developed lands and their investments, therefore, be it

Resolved, That in all such cases we urge prompt and appropriate legislative relief so that those who have in good faith developed such lands shall be protected.

Uniform Systems of Accounting, Introduced by Carl Scholz.

Whereas, The information which the Federal Trade Commission has acquired within the time of its existence has placed it in possession of data and other information on costs which will enable it to do much toward the improvement in conditions of the employes, aid the mine owners and at the same time subserve the interests of the public; and

Whereas, The American Mining Congress, recognizing the many difficulties which confront the mining industry and believes the conservation of life and mineral resources are vital to the welfare of the nation; therefore, be it

Resolved, That we recommend that the Congress of the United States be requested to enact such legislation and make such appropriation as will enable the Federal Trade Commission to devise uniform systems of accounting applicable to the different branches of the mining industry.

Public Land Laws, Introduced by L. W. Trumbull.

Whereas, The increasing expense of courts, schools, asylums, hospitals and other state institutions, the building and maintenance of roads, and the administration of law over its whole area, cannot be supported by a tax levied upon less than one-half of the area of the several states without undue and unfair burden; and

Whereas, The policy laid down by Abraham Lincoln that "The public lands are an impermanent national possession held in trust for the maturing states," and the liberal administration of laws framed to make such policy effective have worked great advantage to the West and to the nation; and

Whereas, The recent restrictive administration of the public land laws and the efforts to make more difficult the acquisition of title to mineral and other public lands in the West have been largely instrumental in preventing settlement, in restricting development and hampering the progress of the mining industry and preventing it from keeping pace with industrial advancement in other lines of effort; and

Whereas, The proposed policy for the Federal leasing of mineral and other lands will keep from the state taxing power valuable property, which should contribute to the support of state institutions, will prevent investment, restrict development, foster monopoly in the hands of those who have already acquired title to the public domain and make necessary a system of Federal control and espionage subversive of free institutions, expensive of administrations and repugnant to the feelings of a free people, therefore, be it

Resolved, That we urge upon the Department of Interior of the United States a more liberal administration of our public land laws, that we disfavor the adoption at this time of any system of Federal leasing of mineral and other lands, or the enactment by Congress of any laws relating to public lands having a tendency to restrict the development of the West.

Resolutions of Condolence, Introduced by Committee on Resolutions.

Whereas, During the past year several members of this Association have been called to the Great Beyond; therefore, be it

Resolved, That this Congress wishes to express, through its secretary, to the families of the deceased the condolence and sympathy of this Congress.

Vote of Appreciation—Introduced by the Committee on Resolutions.

Whereas, The Nineteenth Session of the American Mining Congress, one of the most successful in its history, is this day drawing to a close; therefore, be it

Resolved, By the Congress in session that we extend to the exhibitors and advertisers, who have come here to bring to our attention their respective products, our deep appreciation; to the La Salle Hotel our thanks for the uniform courtesy extended to all of our members; to the committees who have diligently labored for the best interest of the Congress our sincere appreciation; to the coal operators of this state our heartfelt esteem for the many and continued courtesies they have shown us.

Secretary Callbreath was asked to present the paper of Henry Sturgis Drinker on "The Position of Engineers Towards the Questions of Water Power Developments in the West." The situation was summarized as follows:

It is folly for a man untrained in engineering to venture opinions on questions like the conservation, development and economic utilization of our minerals and our water powers which require the judgment and experience of engineers. The trouble with many of the plans for coal and water power conservation proposed by men untrained and inexperienced in engineering and in business methods, is, that their plans are ideal rather than real, their dicta negative rather than positive, and their remedies theoretical rather than practical. You have doubtless observed that the fear that is uppermost with such men is often rather than our public resources will pass into the control of what they term the "monopolistic interests of the few," than the crucial question of what is the best plan or system for the economic winning of our natural resources in the interest of the public. What engineers should urge and impress upon the public mind is the importance of looking at these industrial questions in a wholly cold-blooded, business way—without any obsession or oppression of undefined hysterical fear of the results or dangers of a so-called corporate monopoly that are often as visionary as the nursery tales of bogies to frighten children into being good. Corporations, as we know, are, as a rule, only aggregations of capital to promote some useful industrial or transportation purpose; they are, like other agencies of the day, capable of use and of abuse.

The difficulty, and the probable error, in criticizing all large development enterprises as being so-called monopolies is that the superficial critic is apt to consider and discuss the situation on one side only. The conservation,—the careful mining,—of our minerals, and the economic development of our latent water powers, for instance, can only be managed properly by the investment of large capital, and this can today be supplied only by the association of many individuals having capital to invest, into large corporations controlling such aggregate capital, or by the Utopian plan of state or Federal ownership and the use of the public funds in an industrial enterprise. As to corporations, the stronger they are the more surely are they in a position to handle mining and water-power problems conservatively and economically. The economic mining of minerals—the proper development of a water power site, involve purely expert questions, but it takes capital to command the best expert talent and the investment of large capital to economically develop and erect a plant to produce economical results. Any other course raises the cost of production, and the consumer ultimately pays. As a rule, operations on a large scale, lawfully exercised and regulated (and with the Public Service Commission of today they are surely abundantly regulated), result in conserving our resources for the benefit and service of the consumer and save their waste by the producer.

Dr. Willis R. Whitney, who is doing much of the research work for the General Electric Company in its laboratory at Schenectady, sounded a new keynote in the program of "National Preparedness." "I think I am right," he began, "in saying that the preparation of men for scientific research in America has been inadequate."

May it not be that we are in a state of coma, induced by superficial prosperity and prolonged by the relatively scattered and disorganized conditions of our more recent past? For apparently good reasons, we have of late years entered upon a policy of discouraging the growth of corporations, of strangling the railroads, and of forcibly stopping large water power developments, and now we learn from the press that Germany and England are busy bringing about the union of competing manufacturing companies in order to strengthen home industry.

I want to emphasize the necessity which confronts us of devoting greater attention to natural sciences and to the unearthing of those values of natural knowledge which nothing but mining in fact will provide. I want to see our country get out of the habit of too exclusively awaiting fundamental discoveries from abroad and merely developing them by the application of brute force and high speed.

We need more information on the properties of materials of all sorts in order to suggest their use in places where the needs are often already well in sight. The trial of promising applications is usually easy and not long delayed. It is the fundamental search for properties that is slow and neglected. Our trouble is not that we will not try promising combinations but that we do not know how to project those which are not obvious.

It seems to be the rule that the valuable results come from what appear to be the most insignificant observations of natural phenomena. It was not the density of nitrogen that disclosed all the rare gases, but the small difference which was found between the densities of nitrogen from different origins. It was not the active properties of argon which put it into our incandescent lamps of today but its poor thermal conductivity and the peculiar fact that it did not have the chemical activity of other gases. These are really by-products of properties.

We can all agree on the importance of determining the properties of the chemical elements, because they are few in number and in material things we believe we shall always be confined to them, but the useful properties are infinite in number and the aid we may get from the knowledge acquired by actual experiment or contact with them, is also infinite. One of the most terrible explosives of this superlatively terrible war is a mixture containing apparently harmless metallic aluminum and ammonium nitrate.

In case of danger to our country from war we quickly learn the importance of increasing our navy and our armament, of meeting in kind and degree the menace we imagine can prevail. We all believe in enormously increased expenditure for those plans and devices which students of our situation suggest. We take an industrial inventory and determine where best can be produced the materials most needed in war time. This is only ordinary foresight and in democratic government must be done about as it is being done now.

But even in this undertaking we cannot help noting how dependent we are on foreign nations. This is painfully true for many materials of trade. It has been sufficiently aired in the press. Potash and dyes, nitre and alloys are peculiarly foreign products. In some such cases the cure may easily be affected, in others it may be difficult.

It is well known by mining engineers that the only considerable nitre deposits are in Chile and in case of war we might be prevented from drawing on this supply. For all explosives now used in war, whether it be the old black powder, gun cotton, or the modern tri-nitrotoleul and deadly ammonal, the one indispensable material is nitrate.

But if we would do more research for ourselves we must first look to the training of more of our young men so that they may be fitted and encouraged to take up such work. We must plan for more general scientific education and for training in research. The thousands of young men who take 4 years of study in our colleges must have among them very many whose cultivated instincts would make them tend in this direction if properly directed and encouraged.

Members' Meeting.

Wednesday Evening, Nov. 15, 1916.

President Scholz presiding, the financial report of the secretary and treasurer was read and adopted. The report shows \$1400 in the bank.

Plans for the creation of a Bureau of Mining Economics and a Bureau of Publicity at Washington were discussed.

A nominating committee was appointed consisting of H. Evsmith of Minnesota, S. A. Taylor of Pennsylvania, and A. H. Purdue of Virginia.

Coal Section.

Tuesday Afternoon, Nov. 14, 1916.

C. M. Moderwell of Chicago presided and Alexander Blair acted as secretary.

Papers were read as follows:

"Co-operation in the Marketing of Coal," by Ralph Crewes, Chicago. Discussion was participated in by Dr. F. C. Honnald, C. P. White, Jas. E. McCoy, Thos. L. Lewis, Carl Fletcher, S. A. Taylor, Geo. Otis Smith.

Wednesday Afternoon, Nov. 15, 1916.

Dr. I. C. White of West Virginia presided and Mr. Blair served as secretary. Papers were presented as follows: "The Duties of Mine Inspectors," by J. W. Paul of Pennsylvania; "What Comes of the Benefits of Production Efficiency," by George H. Cushing, Chicago.

An open discussion followed on "The Closed Shop and the Check-off as Related to Efficiency in Mining Operations," and was participated in by T. H. O'Brien, New Mexico; Carl Scholz, Illinois; J. K. Dering; W. J. Snyder, Indiana; Senator Clarkson, Iowa, George H. Cushing, Illinois; F. P. Wright, Kentucky; E. H. Weitzel, Colorado; John P. Reece; S. A. Taylor, Pennsylvania; Mr. Newberger, Pennsylvania; E. W. Parker.

Thursday Morning, Nov. 16, 1916.

W. C. Tucker of Kentucky presided; Mr. Blair acted as secretary. Papers were presented as follows:

"Difficulties I Have Met in Coal Litigation and the Remedies," by R. W. Ropiequet of Belleville, Ill. Discussion was participated in by J. E. Williams, Illinois, and John P. Reece.

A paper on "World Trade Conditions of the Future," was presented by Charles L. Dering, Illinois.

Banquet.

Thursday Evening, Nov. 16, 1916.

Col. George T. Buckingham of Chicago acted as toast-master.

President Scholz in calling the session to order, announced his retirement as president of the Congress and took occasion to thank the delegates and members for their attendance, and to the Chicago committee for their entertainment and arrangements.

In his address on "Co-operation, the Basis of Safety, Efficiency and Conservatism in the Use of the National Mineral Resources," Carl Scholz, said in part:

We are left with the naked truth that we have become a manufacturing nation forbidden at home to regulate output to need and, by commercial treaties abroad, stripped of an overseas market for our factory output. As a nation then we have work to do in setting our own house in order. What are we to do when our tottering business cannot lean upon war orders?

This Congress, which represents the mining industry, cannot evade the responsibilities ahead of it. Much harder work must be done than ever before to secure merely a continuance of conditions, however trying they were, which prevailed before the war. The metal trades must feel especially the new conditions because those who are now our best customers will, when the war is over, become our competitors. They will compete being seasoned by war experience in handling metals and will have acquired that efficiency which is born of hardships. They will practice economy taught by poverty and will display endurance and courage which comes from years of struggle with death as the adversary. Meanwhile, America has had the opposite of these experiences, being satisfied by ease and luxury. How can we face the future unless we pass through some such great change as was suggested by a prominent bishop when he said: "You must be born again." Maybe we must say that to our industries.

It is unfortunate that in suggesting we seize upon the only remedy at hand, I must use a word which has come to be popu-

lar under another and an impossible meaning. Men cannot co-operate successfully if the sole aim is the satisfaction of selfishness. The line between proper co-operation and restraint of trade is as clearly defined as is that between community action to reduce waste and monopoly. That cleavage must be maintained, even as we must differentiate between socialism and democracy, which are in no sense synonymous.

In this larger and better sense, the Congress stands for co-operation. It construes it to be a form of community action participated in equally by the Government, the employer and worker. It must be literally a case of all for one and one for all with the common aim of mutual helpfulness.

In this time, I can think of no greater need we have as citizens, as workers, and as employers, than that which is to work out a plan by which we can co-operate without harm to anyone but with good for all and to be as considerate of those who are to follow as we are to those now here.

The speaker was here interrupted by E. W. Parker, who asked for a portion of the time of Mr. Scholz, and in his usual happy manner made the following appropriate remarks:

Because I always like to speak, I have asked for a portion of Mr. Scholz' time. Now, time is the thing which poets and writers and songsters and speakers have discussed for ages. No subject has received more attention than time. Time and again they speak of springtime, they speak of the gentle spring-time. One poet even wrote a poem about the banks on which the wild "time" grows. Another has said that time was made for slaves, and certainly the object of this attack or spasm has been a slave of duty, a slave to his friends, a slave to his business, a slave to this organization, and surely if time were made for slaves, then time belongs to him.

Mr. Scholz, we hope time will deal gently with you, and in behalf of your friends, the American Mining Congress, I wish to present to you a little piece of time. This little piece of time, which someone has called a repeater, is presented to you. I do not know whether it will repeat, but it has a repeater on the inside. It is engraved and I think I remember what it says: It is:

* *
PRESENTED TO CARL SCHOLZ, THREE TIMES PRESIDENT OF
THE AMERICAN MINING CONGRESS, IN RECOGNITION OF HIS
SERVICES TO THE MINING INDUSTRY.
* *

Mr. Scholz acknowledged receipt of the timely gift in his usual graceful manner.

In an address on "The Federal Government in Its Relation to the Public Land Laws of the West," Frank H. Short of Fresno, Calif., claimed that those of us in the west who have studied this subject believe in conservation in a common-sense way and there is no question but what intelligence should be used in preserving the forests.

We of the West never object to anything that the United States government may do under its constitutional grant of power, but when through the ownership of the public lands they seek to levy upon the industries of our state charges and taxes that they can't levy upon other states, when they seek to impose laws and regulations upon us through those lands, we say that this is an inseparable union of equal and indestructible states and we demand equal treatment, no more and no less.

At this time I want to say to you that I think we are facing some very serious and important problems in America. We all like to talk of prosperity and I am sure I don't like to bring up any ideas of adversity, but I do not think we ought or could afford to quarrel on sectional and divided problems. You know this is the only constitutional form of government of law that exists in the world that has ruled any considerable number of people for any considerable length of time; and with the gathering forces of destruction and with the menace from the outside world, it may be, it may well be, that whether it be on the Atlantic or on the Pacific, we must fight as men have seldom fought before for the preservation of constitutional government, civil liberty and free institutions in this country. It may be so. Let me say to you that while you hear a great deal of talk in campaigns about how rich we have grown, some of the others, and how soft and indulgent and given over to luxury the American people are, I think that is all on the surface. I like to remember that we had our origin as a distinctive race some thousands of years ago, away back beneath the oak forests of Germany and Britain, and while we have yielded to the domination of king or priestly rule sometimes, while we have erred in one direction or another, we have always risen safely over every obstacle, and that all in all we are the most liberty-loving, the most resistless, the bravest, the freest, most intelligent and best race of men that ever peopled the earth in all the tides of time. It makes no difference whether an American citizen comes from Hartford, Connecticut, or from California, it makes no difference, you may talk of the East and the West and the North and the South, but, after all, this is America, dedicated to American institutions, to a free and constitutional government; no matter which way we go—east, north, or south or west—we are side by side at the same little gate when all is done. The ways of Americans may be many but our end will be common and one.

The addresses of Col. George Pope of Hartford, Conn., on "Organized Capital and Organized Labor and Their Relation to Efficiency, Conservation, Better Wages, Better Living Conditions, Lawlessness, Strike Disorders and Industrial Freedom," was an unusually interesting exposition of the conditions that govern employment and labor in the United States today.

Metalliferous Section.

Tuesday, Nov. 14, 1916, 2 p. m.

George E. Collins, of Denver, Colo., presiding.

The paper by C. E. Siebenthal of the U. S. Geological Survey, was read by Geo. Otis Smith in summary form:

The lead content of the ore mined raised from 500,000 tons in the year 1913 to 523,000 tons in the year 1914, which was hardly more than a normal increase, but it went to 562,000 in the year 1915. The recoverable zinc content of ore mined was 406,000 tons in 1913, as against 407,000 tons in 1914; it was 606,000 tons in 1915—a 50 per cent increase, due to the demand from Europe. Both the lead and the zinc industries have been cleaning up in the year of 1916, and there will doubtless be a notable increase in the output each year, more especially in zinc.

The increase in the output of zinc was noticeable, or is expected in the states of New York, New Jersey, Virginia, Tennessee, the Upper Mississippi Valley region, the Joplin region, New Mexico, Montana, Idaho and California. About the only important state I have omitted from this is Colorado. In the Down Town district of Leadville, when that district is drained, the work has begun in the mines there—the zinc output of that district and of that state will be increased, but that will not happen until the year of 1917.

Mr. Siebenthal then gives a full table of the amount of production for 1914 and 1915, and then he summarizes the development in the eastern states.

Mr. Siebenthal this year has been trying especially to work up the reserves to see just how long the United States can keep on with this present high rate of production, or a rate approximating that. Of course, he does not expect it to get a very exact result.

C. A. Tupper of Mining and Engineering World, in his paper on "The Mining Industry—Its Magnitude," gave facts and figures proving the importance of the mining industry and its great earning powers. Mr. Tupper said:

Mining is the second great basic industry of the country. Its magnitude may be partially shown by the fact that for ten years preceding the European war, or up to the beginning of 1915, the value of mineral products in the United States was \$19,793,928,955, or an average of nearly \$1,980,000,000 per year. In the last normal year, which was 1913, it had risen to \$2,439,159,728.

The totals for the several years are as follows:

1905.....	\$1,623,664,785	1911.....	\$1,926,284,008
1906.....	1,903,229,387	1912.....	2,244,033,833
1907.....	2,069,941,398	1913.....	2,439,159,728
1908.....	1,594,696,842	1914.....	2,114,946,024
1909.....	1,886,756,730		
1910.....	1,991,216,220	Total.....	\$19,793,928,955

This represents the amount directly contributed to the wealth of the nation, which, under the stress of war demand and war prices has now increased to approximately \$4,300,000,000 per annum.

But that is only the beginning. In the workings necessary for the recovery of such values, together with others which failed to yield returns, a great quantity of equipment and supplies were utilized, exclusive of food, miners' clothing and living necessities which are naturally covered by wages. Such items cannot be determined with absolute accuracy, but it is possible to compute them approximately—and quite closely—by figuring on a series of average percentage costs for the various years. During the decade mentioned purchases of equipment and supplies made by the mineral properties of this country aggregated not less than \$7,200,000,000, being at present on a basis of \$900,000,000 per annum or more. An amount somewhat in excess of material costs is normally expended in wages, and such proportion for most of the full ten-year period has been greater, so that the total wages paid would be over \$14,000,000,000. Based on the figures thus far available for 1916, it is reliably estimated that about 1,825,000 men are employed in the mines and oil fields of the country. [Taking only the principal items of development, equipment, wages and output, the amount of money put in circulation by the mineral industries of the United States in ten years has exceeded \$39,000,000,000, of which the bulk stands for wealth newly created.]

Even with this magnificent sum, however, only a start has been made; for it will be remembered that the mineral industry is essentially basic, being the broad foundation upon which great structures of other industries are reared. In this respect, while mining stands below agriculture in original output, it far overtops it in secondary products; and the further derivatives of those products reach a total value which is simply stupendous.

Probably few people, even among our leading manufacturers, have tried to realize what the condition of this country would be without its mineral resources or without the development of those resources on an adequate scale.

In the first instance, if manufacturing had been in progress for many years, we would be situated as France is today, utterly dependent on importations for all raw material except what is grown from the soil—with, however, this difference, that manufacturing on a large scale would never have gotten a start in the United States at all. We would have remained essentially an agricultural people.

In the second instance, had our mineral resources not been well developed, we would find ourselves today in the position of Russia.

Does the present situation of either France or Russia—even apart from their war problems—appeal to Americans? If not, we owe it to ourselves to get in mind some proper appreciation of what the mineral industries of this country mean to it.

[One of the most important lessons for the people of the United States, as the late Dr. Holmes pointed out, is to realize the importance of the mining industry; and a means of teaching them some part of this lesson has been found in the publication of dividends paid by the principal mining companies.] The

only earnings ever made public in this manner are those of certain metal mining corporations whose stock is widely distributed, and these, of course, represent a mere fraction of the total mineral production of the country; but, even so, they are sufficiently impressive.

The wonderful earning capacity of American mines can be well illustrated by referring to the dividend disbursements made by 167 companies (all that make their dividends public) during the ten months of 1916 just past. These companies between Jan. 1, 1916, and Oct. 31, 1916, divided among shareholders the sum of \$184,830,127. If the dividend payments of the securities-holding corporations were to be included (as they could right-fully be) the year's total would reach \$223,433,208—a most convincing argument that mining, as now carried on, is the principal reason for our present standing at the head of the world's great industrial countries.

That these companies not only enjoyed a remarkable prosperity during the past 10 months, but also in previous years, is shown by reports made to Mining and Engineering World, that these companies previously paid dividends amounting to \$1,067,277,064, which with the dividends already paid in 1916, makes a total of \$1,252,107,191. This is a return of better than 133% on the combined issued capital of the companies, a remarkable record and one hardly duplicated by any other industry.

The great bulk of these figures for dividend paying stock companies represents metal mines operated solely within the United States. If you added to the exact proportion of that total the actual earnings of close corporations in the same fields and those of coal and other mineral producing companies, you would have an aggregate almost unbelievable. Yet even that is but a fraction of the colossal totals of production and disbursements for labor, equipment and supplies cited at the beginning of this paper.

[No more important work faces the American Mining Congress, and the mineral interests generally, than that of impressing upon the people of the United States the tremendous value of the mining industry to the welfare of the country.]

This will strengthen the hands of the tireless, efficient secretary of the Congress, J. F. Callbreath, in his great work to secure legislation better suited to the needs of the industry; it will bring more encouragement and support from Congress to the U. S. Geological Survey; it will foster the growth of the U. S. Bureau of Mines and it will attract to sound, legitimate mining enterprises the new capital constantly needed for development.

In this the mineral interests will have the vigorous backing of the mining press, and I can particularly pledge that of the one paper, cited above, which has consistently and persistently supported the American Mining Congress from its inception. With a long pull, a stroog pull and a pull all together, there is much that can be accomplished in the immediate future to raise the mineral industries to the plane on which they belong.

Let us try our best to do this.

The paper by Otto Ruhl on "A Tariff for Revenue as Related to a Compensating Duty on Lead and Zinc Ores" elicited considerable favorable comment and the discussion that followed the reading brought forth many interesting sidelights on the subject.

J. W. Kelley of Chicago from results of experiences reviewed conditions in Mexico as they exist today.

As we all know, there exists at the present time in the Republic of Mexico a state of anarchy, but where the country is peaceful, under present transportation facilities, or, transportation facilities as they existed before the warring factions uprooted from their very bed the different railroads, even at that time you could not get ore out except to go and ship it away around to Monterey, or else away down to Vera Cruz, or to Tampico, or else come back to El Paso, where you could get into our own country, paying at the same time a highly exorbitant tax of 2½%.

Our systems of transportation are the greatest in the world, but in Mexico, unheard of conditions exist and some of the mines are as far as 150 miles away from the side of a railroad, others 65, 75, 50 and others within 4 or 5 or 20 miles away, and the ore has to be taken down the tortuous trails of the mountain sides of Old Mexico upon the backs of burros.

During the reign of the Madero government, that is, while the revolution was in existence, it practically stopped everything. However, after he was once elected and placed in power, the mines all opened up and their owners began pumping out the water with which their mines were filled during the time of the revolution. However, due again to the lack of railroad facilities, coal was practically impossible to obtain, due to the great distances from railroad transportation.

I have lived in the country, I know the people and I returned from there but a few weeks ago; returned from the midst of that cataclysm of anarchy, death and fire, starvation and pestilence, and I talked with and listened to many intelligent Mexicans, that is, I listened to and talked with such Mexicans as it would be safe to go among, and at the present time I find that the country is very much split on the question of Carranza. Many regard him as a high-minded benefactor of the poor, while others regard him as a treacherous robber. It is just this division of thought which is creating many factions at the present time.

Now, I have often thought that it is a great pity that something for the sake of humanity, for the sake of these millions of fellow beings, cannot be done, it is a pity something cannot be done for that God forsaken country.

Wednesday, Nov. 15, 1916, 2 p. m.

A. A. Codd of Reno, Nev., presiding.

"The Marketing of Zinc Ores" was discussed in a paper by W. B. Shackelford of Webb City, Mo. He devoted his attention to the sampling and the marketing of zinc ores in the Joplin district, comprising northeastern Oklahoma, southeastern Kansas, southwestern Missouri and northwest-

ern Arkansas. On the plan of settlement he had the following to say:

Taking a 60% ore, we receive \$1 for each per cent over 60% in settlement, and are penalized \$1 for each per cent under 60%. We are allowed 1% for iron. That is, if your ore carried 1½% for iron, you would be penalized 50 cts. The moisture is simply deducted from the total gross weight of the shipment. The mean of the two samples is taken to determine the basis of settlement. It is very seldom that we have differences of any consequence. Sometimes there are shortages claimed in weight, and if indications point to the scales being out of balance, the seller usually makes that good. If the shortage appears to have occurred in transit, the loss is upon the buyer. All settlements are cash upon determination of the assay. That form of settlement is used entirely in this district, and I presume originally started from the fact that in the earlier history of that district many of the smaller operators produced zinc ores. They were men that had very little means and they required the cash, so they could meet their payrolls and pay their supply bills. That system is still in existence today, and when we appear with our assay and check with the buyer, we immediately receive a check for the full value of the ore.

I know of no contracts in force in our districts, although I think at one time there were some contracts in existence in Oklahoma that were made by smelters who purchased largely western ores. I understand that all such contracts have expired.

The penalties sometimes apply to excessive lime in the ore. Some smelters refuse to buy any ore that carries over 1%, and some will limit you to 2%, but you are usually penalized for lime for anything above 2%.

Henricus J. Stander's paper on "Flotation" was well received, it being the first general paper of its kind to be read before the American Mining Congress. The importance of the subject and coming from an authority like Mr. Stander, warrants its publication practically in full:

Judging from an experience in which I came in contact with not only most of the practical flotation men in this country and Canada, but also with most of the scientific investigators of flotation, the practical man in charge of the flotation machines plays a far more important part in the actual development of the process than we give him credit for. To give you an illustration: In a 1000-ton per day flotation plant, in which a special flotation expert was employed, who had the very best co-operation of his assistant and of the chief assayer, I found, after spending 7 days in their laboratories and plant, that the man who could give me the best information, without any doubt in his mind as to what his answers implied, was the flotation man in the morning shift.

He knew exactly what to expect under any given condition. His knowledge came, of course, only from experience. It is the help of such men that the scientific investigator needs more than anything else. I myself have put a year on flotation in a laboratory, and have carried on numerous physical and chemical experiments in relation to this subject. Yet I must admit, after having come in touch with numerous of these practical men, and having taken note of what they had to say, and giving them full credit for their practical views gained perhaps by hard experience, that many points seem far clearer to me now than when I was trying to solve it all in the laboratory.

I am not trying to discourage any type of investigation in the flotation field, for we need as much as we can get and especially at this time, but I am trying to show that the scientific investigator can gain a whole lot, in all cases, when he keeps in close touch with the practical flotation man and his views. Simply because a man cannot talk to you in terms of particles, occluded gas, electrical theory, surface tension, oil film, etc., is no reason in the world why you should not give him full credit for what he knows, for in most cases he knows his subject from a practical viewpoint better than you. It is only through a co-operation of all parties concerned that we can ever expect to reach a final and perfectly satisfactory solution of the problem.

Those of you familiar with the flotation process will agree with me, I believe, that this subject has been credited with an undue amount of phenomenal and unexplainable obstacles. That those principles upon which the very existence of the process depends are not to be explained by any one law is perfectly clear to most of us. Yet the number of flotation pessimists form too large a group; for upon a careful step-by-step analysis of the actual facts in the case, it does not seem as if we are so very far beyond our depths when trying to formulate the courses, not course, of flotation.

In this brief talk, it is impossible to touch on all the points, but I should like to direct your attention to some of the very essential ones.

One of the first things that draws our attention is the fact that sulphides are peculiarly suited for flotation treatments. What is it about the sulphide that makes it so different from the silica? Applying a process of elimination, we find that gravity cannot enter into this discussion. What else do we know about the sulphide and silica bodies, respectively? We know that a silica particle absorbs water much more readily than does the sulphide. This is due partly to the property of porosity as manifested by these two respectively. The sulphide seems to constitute a much more compact and solid body. The very fact that the silica gets wet or absorbs the water so rapidly explains why it should break the water film and become literally "soaked" with water. The sulphide, on the other hand, behaves differently, and even when in suspension in the water, it appears to have more of a film of water around itself than having, like the silica, the liquid throughout its entire system. This may seem fairly theoretical, but we cannot, of course, conceive of so small a particle of either silica or sulphide, but that it is made up of an extremely large number of molecules of either SiO_2 or, say, PbS , respectively. The particle of silica that passes through 200 mesh is far from presenting as compact a body or system as in the particle of sulphide crushed to the same mesh. This to me is one of the very important factors in the flotation process. Going back to the old surface tension flotation process, we find that the separation depended on the fact that the silica, as soon as it strikes the water film, sinks into the liquid, whereas the sulphide particle does not. Now why

should the silica particle sink? First of all, it is necessary for the silica to pierce the surface of the water. Although much attention has been paid here to the so-called "Angle of Contact," I believe the fact that the silica absorbs water so readily plays the main role here.

The porosity of the silica particle, its exterior outline (embodying its so-called angle of contact), its lack of presenting a solid, compact body, will all help it in breaking the surface film of the water, and furthermore allow the liquid to enter its very pores. And this, as you saw, is not the case with the sulphides.

I am not going to bother you here with the duty of oil or acid in this process, for we have been shown that a truly flotation separation can be effected without the use of either or both of these. The oil and acid both will have their respective effects on the surface tension of the liquid and on the materials in the liquid, but in this case foreign substances are employed to get as near as possible perfect conditions. So the discussion of these and their functions is at present outside of my subject, as I am trying to analyze the actual essentials in the so-called flotation phenomenon. To see what these essentials are, it appears as if it is only necessary for us to study the case where this strange process actually takes place in virtue of the properties of the substances in the ore and the water employed. Such is the case in the purely surface tension process. To show you that oil, acid or chemicals are what we can call accessories, and very important accessories indeed, when we are trying to perfect the process, I need only remind you of the present Wood flotation machines and others of the same nature. I had the opportunity to watch the machines of Henry E. Wood in operation in his testing laboratory at Denver. With regard to this machine, I can say that I believe that Mr. Wood has succeeded, perhaps better than anyone else, in making a machine in which the sulphides get an almost perfect chance to stay on the surface and sink into the water; but the biggest thing for the inventor to overcome in this particular process is to make his machine such that the sulphides get as small a chance as possible to become wet.

In the agitation process (mechanical or pneumatic), the sulphides are already in the liquid when they enter the flotation machines, and in this case the inventor tries to make a machine with perhaps the use of outside help, by employing oil, acid or some foreign substance, in which the sulphide will again get a chance to come on the outside of a water surface, although this water surface may take the shape of an enclosing wall around an air-bubble in the liquid, either beaten in by mechanical agitation or passed in by means of what we call pneumatic agitation. The use of oil in this case may help to strengthen these numerous spherical water surfaces around the gas bubbles, or may enable the sulphides better to withstand the tendency of the water to wet them. The silica particles are drenched with the liquid, and so the oil may have a rather slight effect on them; yet I believe the effect of the oil on these numerous water surfaces (or what I called in an article "water-air interfaces") is far more important in the process than its effect on the silica and sulphide as individual particles.

Whatever methods we may be using or whatever improvements in the process we may employ, they all seem to tend to accomplish one thing, viz., to give the sulphide particle the best chance possible to rest on a water-surface, whatever slope this surface may take. We create such surfaces by agitation, mechanical or pneumatic, by the production of gas in the liquid through the action of an acid in some material in the ore, such as carbonates, or by freeing dissolved gas through a decrease in pressure (vacuum action). In some cases we use only the exposed water-surface, in which case it is necessary to pay supreme attention to the way in which the ore particles enter on to the water surface. But in all cases, the sulphide must be given a good chance to assert its property of floating on a water-air or water-gas surface.

That the principles of many of the advanced theories play a part and help in the procuring of this desired condition, I firmly believe. I do not, however, believe that any one principle, such as "occluded gas," explains the existence of the process. Different means may be used to attain the same end, and consequently different factors will enter into these different means employed; yet to understand why flotation takes place it is necessary for us to lay bare only those very essential things necessary to produce a flotation action. This we find in the very simple surface-tension process. Coming down as far as this, we are then confronted with the question: "Why does the sulphide float on the water surface?" And I repeat that to me the following properties of the sulphide explain its behavior:

1. Its slight degree of porosity, or its obstinacy to let water enter its system.
2. The compactness of the molecules comprising the sulphide particles as compared with that of the SiO_2 molecules. And this would, of course, favor the above mentioned obstinacy.
3. The exterior form, shape or outline of the finely crushed sulphide particle being such as not to be near so liable to pierce a water-gas film as is the silica particle.

I must again repeat that the very fact that the silica seems so eager to get wet, in other words, absorbs water so very readily in its pores, contrary to the behavior of the sulphides, that this property is of utmost importance in the flotation process.

Some of you may be eager to ask: "But why is it that some sulphides are more floatative than other sulphides, since, according to this they would then all come under one class?" Well, it is only necessary for us to recollect that the molecules of one sulphide, say, galena, will not be exactly as compact in comprising the particle of galena, as are, say, the molecules of MoS_2 in the particle of molybdenite. The sulphides will fall in the same group as far as their porosity, compactness of molecules and exterior surfaces are concerned, but the slight variations in these properties as manifested by the different sulphides would warrant different degrees of amenability to the flotation process for the different sulphides.

The behavior of the different sulphides as far as these properties are concerned would also make it necessary that a definite sulphide ore should be crushed to a definite degree in order to obtain the best results in flotation.

I believe you have heard enough on the theoretical end of the subject, and it may interest some of you to hear about a few of the most interesting things I saw in visiting the flotation plants in North America. Perhaps some of you do not as yet know that a 1000-ton flotation plant is in operation in Alaska. Should you care to read an account on Alaska flotation, I refer

you to the Alaska flotation article that appeared in the Nov. 11 issue of the Mining and Engineering World.

Perhaps the most interesting case I saw was up in the Cobalt district, Ontario, Canada. Most of the companies are treating their old tailing dumps. The concentrate may run as high as from 250 to 300 ozs. in silver. The concentrate will also carry approximately 2.0% copper, 0.5 to 1.0% nickel, 2.0 to 2.5% cobalt, 9.0 to 10% arsenic, 17 to 18% iron.

Most of these companies never knew that their ore contained any traces of copper, but when flotation was started to make a 300-oz. silver concentrate from a 10-oz. tailings, many were surprised to find copper appear in the concentrate. The concentrate is, of course, sold only for the silver values, as, according to the composition of the concentrate, the other metals are of no value in such a combination. Perhaps it may be made clearer by directing your attention to the Mond Nickel Co.'s problem. I warn you all not to ask me any detailed questions with regard to the nature of the ore and the troubles encountered in the flotation experiments, as it is not the policy of this and most of the other companies up there to allow detailed results to be given out. Yet I may state what their problem is. The object is to bring about a separation of nickel from the other metals, particularly the copper. Should any flotation investigator, whether a university research man or an employe of the state or government, ask me to express my views on the best and most interesting topic to work upon, I would immediately suggest the study and attempt to solve this problem: The separation, by flotation, of nickel from an ore carrying the sulphides of nickel, copper and iron. The problem would, of course, resolve itself into a preferential process. Preliminary roasting, the use of a chemical and the effect of oils, acid and alkali would all be points that would come under this work. The solution of this particular problem, and similar preferential-flotation ones, would be far more valuable than most of the theoretical problems that some of the investigators are now trying to solve.

The paper by D. A. Lyon and O. C. Ralston of the U. S. Bureau of Mines on "The Present Status of the Ore Flotation Process" was read by H. I. Seaman. According to the authors:

Flotation as practiced today is a method of causing one mineral or another to stay on the surface of water or other liquid or to be entrained in the froth lying on the surface of water or other liquid. Only certain minerals will so float and the remainder of the finely ground ore sinks. Flotation finds its present application in the recovery of sulphide minerals or of native metals from a finely ground pulp. Such a finely ground pulp has for many years been known as slimes and has often been a source of much trouble and loss due to its finely divided condition.

Previous to the development of flotation no process for successfully extracting slimed values from low-grade ores existed. Flotation is needed as a process for treating such material. Now that it has been developed, its principal applications are to the following materials.

(a) Accumulations of old tailings containing minerals which were not recovered at the time the ore was treated by ordinary gravity concentration methods.

(b) Tailings from ores now being treated by ordinary gravity concentration processes, for the recovery of the value not recovered by the gravity concentrating machines.

(c) Ores containing valuable minerals in such small crystals as to necessitate very fine grinding in order to permit of the valuable particles of the ore being separated from the gangue. It is, of course, understood that this applies to only sulphides or metallic minerals.

Several different kinds of flotation have been proposed and used, such as film flotation, bulk oil flotation, and frothing flotation. This last type of flotation is the one largely responsible for the great metallurgical advances which have recently been made in the treatment of non-ferrous ores and is now practically the only commercially important method of flotation. A frothing agent, usually an oil, or a substance closely relative to an oil, is used in order to make the water of the pulp froth easily. In addition, the substance added must be such that the valuable minerals will adhere to air bubbles introduced into the pulp. These air bubbles in rising to the surface must carry only the valuable minerals and the froth formed on the surface can be allowed to overflow or to be raked off in some manner, separating the valuable minerals from the gangue. Hence, the first operation in flotation after the ore has been finely ground in readiness for the application of the process is the mixing in of the "oil" and other addition agents. Whether rightly or wrongly, flotation men have come to call this operation emulsifying of the oil. Whether it is emulsion or not, the oil is distributed throughout the ore very thoroughly by mechanical or pneumatic methods of stirring. A soluble frothing agent can, of course, be very easily mixed in with the pulp, but when an insoluble frothing agent is used, the pulp usually needs considerable mechanical beating. The fact that very often only one pound of oil, such as wood creosote, or coal creosote, is used for every ton of ore, which is suspended, say, in four tons of water, makes considerable stirring necessary in order to divide up this oil equally throughout the pulp. Just exactly what function the oil performs is still obscure.

Oils have been classified as frothers and collectors, because some oils make abundant froth but collect very little mineral into the froth, while others seem to have the property of collecting plenty of mineral, but do not tend to froth well. The presence of both properties in an oil, or the use of an oil having each of these properties, seems to be necessary. Occasionally an acid or an alkali or various metallic salts are added. There is a serious question as to the feasibility of flotation in perfectly pure water. Many instances are known where the addition of an electrolyte of one type or another has improved the flotation work, but the reason is not clear. It is possible that acid helps clean off the surface of the particles of sulphides in case they are partially oxidized, and when a better recovery is effected by the addition of an alkali, something takes place, but at the present time nobody knows what it is.

The operations of mixing in the oil and introducing small air bubbles to form a froth, and finally separating the froth, are performed in machines of two broad classes, namely, mechanical and pneumatic.

In the mechanical machines, the mixing of the oil and the introduction of air bubbles takes place usually simultaneously. This is generally effected by a rotating member of one type or another, so arranged that in its rotation air bubbles are beaten into the pulp. As examples of the most successful machines performing this operation are those of the Minerals Separation Co., the Janney machine, and the Krout & Kohlberg machines. After beating the air into the pulp in such machines the pulp is allowed to pass into a spitzkasten where the froth is allowed to rise to the surface and be removed.

There are likewise three general types of pneumatic flotation machines, namely, the Callow, the Inspiration and the Cole-Bergman machines. In all of these the oil must be previously mixed with the ore by any method, while air is introduced through any kind of a porous medium, such as a canvas blanket, on the bottom of the machine.

The present status of the mechanical side of flotation is the designing of new machines along two general lines, namely, those which will consume less power, or less oil, than the earlier types of machines. In other words, one of the greatest advances now being made in flotation is in the designing of machinery.

After the froth is carried off, or flows off from a flotation machine, it must be broken down and dewatered, leaving a concentrate to be sent to the smelter, or otherwise metallurgically treated. At first, considerable difficulty was met in the breaking down of froths, but it is believed that there are now appliances developed which will break down almost any froth. The use of oils which will give an easily handled froth is one thing which is to be considered. A finely divided jet of water issuing from various patented nozzles, such as garden spray nozzles, has been found to be a very efficient breaker of froth. Passing the froth through a bucket elevator has been known to be a good method of breaking it up. Almost universally the pulp resulting from breaking down and concentrating the froth is dewatered in such apparatus as the Dorr thickener, to a consistency which can be filtered. Vacuum filters have become very popular in the filtering of flotation concentrate, especially the filters of the continuous type, such as the Oliver and the Portland. However, they do not give concentrates with as low a percentage of moisture as do the pressure filters, where high pressure can be used in blowing out the water from the filter cake. In some cases it will probably pay to even dry out the moisture in filter cakes in order to save freight when shipping the concentrate to the smelter. As the material is very finely divided, tight railroad cars are necessary for its shipment.

The effect of flotation on smelter practice has been considerable in copper metallurgy and promises to cause extensive changes in zinc and lead smelting practice. The finely divided flotation concentrates are not adapted to smelting in a blast furnace because of the formation of too much flue dust. In copper metallurgy the trend had been toward reverberatory furnaces before flotation was developed on a large scale, and the effect of the sudden development of flotation was the almost complete change to the reverberatory furnace. The reverberatory furnace smelts flotation concentrates with very little previous preparation. The most serious problems in the treatment of any flotation concentrates are the roasting problems. In lead metallurgy it is possible to pass this material over a Dwight-Lloyd, or other centering machine, and obtain a product adapted to blast furnace smelting. It is possible that this could be done in copper metallurgy if the sulphur content of the material were not too high. In the case of zinc sulphide concentrate, the case is not quite so easily handled. The fine subdivision of the zinc sulphide should lead to new methods of roasting and smelting zinc in order to prevent the dusting losses during roasting. In the field of gold and silver it has been found that flotation is a more economical process than cyaniding for many ores and the effect will be the sending of flotation concentrate to the lead and copper smelters for the extraction of the silver and gold contained in them. It would seem that the present state of the art is such that further important developments in smelting practice are liable to take place in the effort to meet the difficulties encountered in treating flotation concentrate.

As intimated above, the flotation process at the present applies mostly to sulphide ore, notably of zinc, lead and copper, although the process seems to be well adapted to the concentration of silver sulphide ores and considerable success has been had in concentrating gold ores with or without the presence of pyrite.

Notable installations where zinc sulphide is being floated are the Butte and Superior at Butte, the Mascot in Tennessee and the Interstate-Callahan in Idaho. Galena is being successfully floated in the southeast Missouri district and in the Coeur d'Alene district of Idaho. Copper sulphide ores are being most successfully treated at Anaconda, Inspiration, Chino, etc. Silver and gold ores are being treated with success throughout Colorado and Nevada.

In the copper country they are finding that the finely divided native copper is also amenable to flotation. During the past year considerable experimental work has been done in flotation of carbonate ores of lead and of copper with the promise of considerable success. This flotation has been accomplished by first treating the ore with the solution of a soluble sulphide such as sodium or hydrogen sulphides. The flotation of the artificial sulphides so formed seems to be a comparatively simple process. While the present state of the art has not seen the successful commercial accomplishment of this method, it is probable that the immediate future will see flotation of carbonate ores of both lead and copper. All attempts at the flotation of carbonate ores of zinc have thus far failed.

We are informed that important developments are on foot making possible the concentration of iron oxides such as magnetite and scheelite and fluorite, and such related minerals which break up with marked cleavage planes.

Very little is known as to the "why" of flotation. We only know "how." During the past year some very important theoretical papers have appeared, but the discussion of the underlying principles involved in flotation has only begun. We do not know enough of the properties of the various oils used and we do not know what becomes of them during flotation. We do know why certain minerals will stick to air bubbles in water contaminated with such oils and it is probable that there are too many things involved for a very immediate complete scientific explanation of the process.

In spite of lack of knowledge as to the underlying principles,

its scope is being rapidly widened and it seems safe to predict the commercial success of the extension of the process to flotation of lead carbonates, and of copper carbonates during the coming year. The solution of the problem of the mixed sulphide and oxidized copper ores, so common in Arizona, also seems to be nearly in sight. The extension of the process to the flotation of non-sulphide minerals of a valuable nature seems to be a more remote possibility, but there are reasons for thinking that a better understanding of the theory of flotation will finally result in the development of methods which will allow the flotation of any kind of mineral. Differential flotation of two floatative minerals in the same ore is at present only mildly successful and we feel justified in predicting important developments along these lines as well. The art is still in the stage of development. It is experiencing a vigorous youth and its full growth has by no means been obtained.

Charles F. Willis, speaking on "The Value of State Organizations," claimed that the reason why mining is not getting its share of recognition is the fact that there is a lack of organization and co-operation, and advised the learning of the lesson from the farmers, whose conditions are envied.

Thursday, Nov. 16, 1916, 10 a. m.

In calling the meeting to order H. I. Scaman, who presided, announced the belief that there should be some forceful revision in the method of giving out subjects to the big men of the country to discuss, and then having the big men not to show up.

This conference is attended by men from all over the United States, who come here from great distances, and who come here for the very purpose of hearing these talks, often leaving their businesses many times at great sacrifice, merely to listen to the papers by the big men of our industries who are announced weeks and weeks before, weeks and weeks in advance, to give us some paper of real interest, because it is only those men who have given the matter long months and years of study that can discuss it properly and answer our questions. For instance, I myself am very much interested in Frederic Lalst's development at Anaconda, and I personally have given up matters of considerable importance this morning to come here and listen to his paper, but he is not here. Neither has he deigned to tell this conference anything as to his whereabouts or as to his intentions. Now, I am going to propose at some subsequent meeting that a revision of this method be made, so that we will have these men right at our meetings, Johnny-on-the-spot, or else we will have something in the way of a paper here from them.

The report of the Committee on Revision of the Mineral Land Laws was read.

According to a paper by Fred F. Van Wagenan of Denver on "The Prospector and the Mining Law," by excluding extralateral rights, the rights to follow a vein outside the side lines of a claim, from the Federal mining law, and change its simple provisions for the initiation and maintenance of titles, the prospector will disappear. With his disappearance, discovering (except by accident) will cease. Then as our known ore bodies become exhausted, production will decline, as it has elsewhere, and the magnificent industry that our free laws have created will slowly, but surely, dwindle to the status already reached in British Australasia, and to that which is approaching in Canada.

Oil and Gas Section.

Tuesday, Nov. 14, 1916, 2 p. m.

Judge Short presiding.

In a paper on "The Authority of the State to Tax Mining Property on Indian Lands," Judge J. G. Gamble of Des Moines, Iowa, reviewed with some detail the various decisions in which it was established that instruments of the general Government are immune from taxation by the several states. Mining and oil leases on Indian lands are made by the Government under the Curtis Act, royalties, etc., all going to the Indians or rather to the fund held by the Government for its wards. Thus it was also held in another famous case that an attempt on the part of the State of Minnesota to tax securities owned by its citizens, but issued by a municipality situate in Indian country which in time gained its power to issue the securities from the Federal Government, is void. From this point Judge Gamble shows that the Government in its administration of Indian lands has vastly increased the amounts set apart for general service, maintenance and supervisory purposes. In this respect the officials do not differ from those of American municipalities. And finally Judge Gamble proposes what he believes is a decided improvement on methods of taxation. He be-

lieves there should be created in each taxing district a board consisting of tax payers to whom the administrative officials should submit an estimate of their requirement of funds for the ensuing year, together with a financial statement showing among other things, the resources of the municipality other than from taxation, and if such board was invested with authority to review such an estimate and reduce the same, and not increase it, as their judgment might dictate, and thereupon was empowered to lay the taxes necessary to meet the estimated requirements as approved by it, it would seem to him that there would be an added assurance to the tax payer that he would be subjected to no such extravagant expenditures as is possible in certain communities now.

In a paper on "The Relation of the Federal Government to Western Oil Production," Governor James N. Gillett reviewed the oil situation as it affected the public lands in the west. As early as 1909 the conclusion was reached that something ought to be done by the national government to conserve the oil resources of the country, and to keep such a control over those resources that there might be prevented monopoly and waste and an over production. He discussed the various withdrawals covering oil lands and as to what disposition was to be made of them by the government.

The paper created considerable interest and brought forth extended discussion by delegates and members, including J. C. McDowell, Judge Short, Louis Titus, Dr. Norman Bridge, and Max W. Ball.

At the conclusion of the paper the following resolution was read and adopted.

Be it Resolved, That this Congress is deeply interested in the just operation of the mining laws. As a result of certain orders of withdrawal by the President and legislation by Congress, many persons, who at great expense, and, as adjudged by the courts, in good faith have developed the oil lands of the country, are threatened with ejection and forfeiture of their developed lands and their investments, in all such cases we urgently urge prompt and appropriate relief legislation so that those who have in good faith developed such lands shall be protected and shall receive prompt and appropriate relief.

Wednesday, Nov. 15, 1916, 2 p. m.

Dr. Rittman in his paper, "Through the Use of Petroleum," showed that the annual consumption of dyes in America is, roughly, from 100,000 to 125,000 tons.

Of this total amount 90% is made up of two colors. Sixty per cent of all the colors used in this country are black, 30% blue, and the numerous other colors are in the remaining 10%.

We hear all kinds of opinions and estimates regarding the importance of this dye industry, some believing that the very foundations of the making depend upon it, others again believe now that in terms of dollars and cents it is no more important than Woolworth's candy item a year. True, it doesn't amount to more than Woolworth's candy item, but it is wrong to consider it in that light.

The importance of the dye industry is more in its relation to other industries, such as the leather industry, the textile industry, and more particularly the explosive industry. The world has learned from a military point of view that Germany's wonderful dye industry was in reality an explosive industry.

It is very natural that these two industries should run hand in hand, because they use identically the same materials to start with, and the processes of manufacture are practically the same up to the very end.

Therefore, we have the close relation between these two industries, first, because they use the same materials, second, because they are manufactured by the same processes. The same equipment that makes the dye materials makes the explosives, and it is a matter of a week or two to convert a plant from one into the other.

In concluding his paper Dr. Rittman held that there is no fundamental division scientifically between coal, lignite, peat, shale, oil, gas. It is a question of volatile matter or a question of hydrogen relative content, because hard coal is the one extreme, methane is the other extreme. Twenty-five per cent of the methane is hydrogen; practically none of the coke is hydrogen. None of the hard coal is volatile, or all of the methane is volatile. It is a case of getting a blend between, that is, on the extreme substances. Is it possible to make one into the other? Not at all. Nature has simply done the same, but scientifically the mere possibility has conceived the possibility in very many cases. So it resolves itself into a natural working out by a study of the laws of physics and chemistry, a study of the laws of nature, and working in sympathy and harmony with those laws.

"Geology In Its Relation to the Oil Industry" was the subject of a paper prepared by J. C. McDowell of Pittsburgh. A summary of the paper follows:

Oil and gas are found in practically every formation porous

enough to contain it through the entire geologic series. But profitable commercial deposits are found only when the formation containing them is enclosed within an impervious strata of rock or shale, usually the latter. It is for this reason that the anticlinal theory first promulgated by Dr. I. C. White about 1880 has been gathering strength in late years. Dr. White discovered that the production was generally found associated with anticlines or earth folds, gas being in the upper part of the anticline; oil, the next heavier, below the gas, and beneath the oil, the salt water.

Perhaps it might better be said that in recent studies the application of the anticlinal theory has been more fully developed, and accumulations are found in places where the theory apparently does not hold, but upon further study a trap or some condition similar to that produced by anticline is found to be present.

Very few, if any companies, however, applied geology greatly to wild-cattling work.

In fact as each producing section of the country appears to offer its own peculiar problems of relationship of deposit structure, it is practically necessary to study each field by itself; but the more this is done the more apparent becomes the fundamental uniformity along certain geological lines.

Probably the most successful application of geology to gas and oil production is that of the last few years in the Mid-continent field in Kansas and Oklahoma. It is safe to say that during 1915-16 several million acres of land have been leased on this trend, and strange to say not only has Kansas acreage been brought back into demand after years of absolute condemnation as worthless for oil and gas purposes, by practically all of the larger producers, but record prices for undeveloped leases are now being paid in that territory. This condition has been brought about by discoveries made along a strictly scientific basis and by men who had faith in the correctness of the anticlinal theory.

By this work were opened three prolific oil and gas pools now among those attracting the attention of the entire oil fraternity—the Augusta pool, the North Augusta pool and the Eldorado pool, all of Butler county, Kan., which represent a good individual example of geology applied to the oil industry. After several years of unsuccessful attempt to open the Augusta gas pool along the customary practical lines, and this field abandoned several times as small, spotted and of no great consequence, methods of geological disclosures were attempted which were very successful from their earliest application in 1913 until today. The earliest attempts were made by taking the level, or altitude at the mouth of each of the wells drilled, whether productive of gas or oil, and plotting an arch representing the top of the gas-bearing sandstone stratum from the well logs or drilling records, taking the cross sections at several points and indicating the true axis of the anticlinal dome, and thereby under a short period of time the field was extended several miles in length by actually producing wells.

Later a carefully prepared planed table survey of the structure was made, using the Fort Riley limestone outcropping at the surface as a base or datum on which to plot structural contours, thus disclosing a dome or trap extending in an irregular shape for seven miles in length and two and a half in greatest width.

It was very apparent that with careful geologic study upon the sound lines, that practically all of the main productive fields of Kansas and Oklahoma could have been forecasted and opened strictly upon geological evidence.

In general it must not be understood that such forecasting is a simple matter, for it is not. At best there are many chances of failure, even after a possible trap is disclosed upon the surface of the ground. Not only is there a danger of the trap flattening before porous strata are reached, but there may be no porous strata underneath. Again there may be, but filled with salt water; again there may be some denser impervious area intervening on the slope preventing the oil and gas from collecting in the dome or trap, and last there may be no gas or oil in any of the formations tapped.

Only patient, careful thought and study can avail.

R. L. Welch had for the title of his paper "Practical Phases of the Standard Oil Dissolution, and the Necessity of Combinations Among Independent Producers to Meet Unfair Competition."

A paper on "Oil Storage" prepared by Garrett B. James of Chicago claimed that the two main points to be considered in the storage of petroleum are evaporation and fire hazard.

The loss of the lighter or more volatile constituents of the oil lowers its value to a more or less marked extent. Evaporation from loose top steel tanks has been as much as 2,000 to 2,500 bbls. in 5 months. Evaporation from steel tanks with gas-tight steel roofs has been comparatively low for the same period. The saving by the latter method would probably cover the additional cost in construction of the tight roof in less than 2 years.

The most effective means known of reducing the fire hazard of oil in steel storage would be the equipment of all-steel tanks with gas-tight steel roofs, properly vented so as to eliminate any possibility of back-firing tanks to be electrically grounded.

As a thoroughly-grounded gas-tight tank of metal is safe from damage by lightning and will also reduce evaporation losses to a marked extent, this is considered the best form for oil storage.

In his paper on "Remedial Legislation for the Benefit of Oil Companies," Roy N. Bishop, president of the Oil Industry Association of California, summarizes the situation as follows:

Under the Act of Congress passed Feb. 11, 1897, entries upon and patents for oil lands can be made under the provisions of the laws relating to lacer mineral claims. It was found that the law was a misfit even in the opinion of the Secretary of the Interior and could not be properly applied to the prospecting and developing of petroleum lands; but acting

under the assumption that the government would do no wilful injustice where actual prospecting was in progress many valuable pieces of land were entered upon by men who expended, in many instances, their entire fortunes. New oil fields were discovered, splendid properties were developed and a great industry given to California and the Nation through the courage, optimism and pluck of these men. The development of one oil field encouraged men to further penetrate the mountains and look for others. In the summer of 1909 they were in the midst of this work when in September 3,041,000 acres in California and Wyoming were withdrawn from entry. A divided Supreme Court declared the withdrawal legal.

Ever since the withdrawal the conditions in the oil fields of California have been chaotic. No new work is being done, great losses are being suffered and bankruptcy faces many who but a few years before went upon government land in the best of faith.

What is going to be done for these men? What relief should Congress give them in the oil-leasing bill now pending in the Senate? Secretary Lane in his report for 1915 says Congress should prevent "an unnecessary injustice to those who have invested many millions of dollars under a mistake as to the law." The House has recognized these equities. The Senate Public Lands Committee favors a like provision. Now comes opposition to the relief provisions of the bill from Gifford Pinchot and a few other ultra conservationists, based upon the cry of "wilful trespassers and looters of the public domain." Two federal judges have dealt with this assertion. Judge Bean in the case of the United States versus the Midway Northern Oil Co. says: "The defenders were not wilful trespassers but relied upon the law and were honest in their belief that they were within their rights." Judge Bledsoe's decision in the case against G. W. McCutcheon is just as emphatic in his statement.

Thursday, Nov. 16, 1916, 10 a. m.

"Adequate Acreage and Oil Conservation" was the subject of a paper by Max W. Ball of the U. S. Bureau of Mines. Mr. Ball decried the enormous wastage now going on and cited figures from various authorities that at the present rate our oil supply—7,701,000,000 bbls.—would last but 29 yrs., based on government figures of resources now available. He emphasized the necessity of conservation:

It is evident that here is a resource the use of which is rapidly increasing, the dependence upon which is well-nigh universal, and the readily available supply of which is limited. There could be no situation calling more clearly for prevention of waste, economical production, and careful use—principles of wise development and proper utilization which we comprehend by the word "conservation." If the American people have need to practice conservation with regard to any natural resource, it is with regard to their supplies of oil and natural gas.

Are we practicing this conservation? Within the last few weeks I have seen millions of cubic feet of natural gas wasting into the air—gas so rich in gasoline that it dripped from the trees like an April shower. I have seen wells capable of yielding 40,000,000 cu. ft. of gas each being deliberately drowned out by pumping water into the gas sands. Reckless drilling, defective casing, careless plugging are flooding great areas with water and losing forever enormous quantities of oil. It has been testified before the Corporation Commission of Oklahoma that ordinary methods leave from 25 to 85% of the oil in the ground, and this estimate is concurred in by careful engineers and practical oil men. Think of it! Twenty-five to 85% of this valuable resource left underground, chiefly through ignorant, careless, wasteful methods.

Nor are these underground losses the only ones. When the oil is brought to the surface before transportation and market are ready for it, it must go into storage. Indeed, in many fields oil has been produced before storage was available and millions of gallons have gone down the streams or seeped away from earthen reservoirs. Even when the best steel tankage has been provided evaporation losses still go on. Cushing crude stored in steel tanks for a few months lost approximately a fifth of its gasoline content. The State Mineralogist's office of California has estimated that even with the heavy oils of that state the loss by evaporation represents perhaps 25% of the total value of the production at the well. An official of one of the largest companies in the Midcontinent field recently told me that last year fire destroyed 6% of his company's production.

Just consider these examples: 25 to 85% left underground; 20 to 25% of the value of oil produced lost through evaporation in storage; 6% of stored oil lost by fire! These losses are staggering and are not exceptional! What a small percentage of this wonderful natural resource is saved to run your machine or to deliver goods at your door, or to plow the fields from which your food must come!

In concluding, Mr. Ball said:

If you would prevent waste of oil and natural gas, if you would do away with careless drilling methods, excessive production charges and storage losses, if you would insure the production of the maximum amount of oil at the minimum cost, if you would help to maintain a reasonable price for petroleum and its products in the years to come; then do your part in creating a public sentiment in favor of adequate acreage. You may not find it a popular propaganda just now. You will doubtless be accused of advocating monopoly and probably branded as a corporation partisan. But if you take one step toward imbedding the acreage idea in the popular mind, or incorporating it into state legislation, or embodying it in oil-field practice, you will have assisted in conserving the oil and gas deposits of the United States, and will have rendered a valuable public service.

Dr. David T. Day had prepared a paper on "The Chemical Possibilities of Petroleum," but owing to the shortness of time was read by title only as was that of Franklin D.

Roosevelt on "The Naval Oil Reserves as a Necessity to National Preparedness."

"The World's Oil Supply" was discussed in a paper by Ralph Arnold, New York, which concluded the sessions of the Oil Section.

Smoker.

Tuesday Evening, Nov. 14, 1916, 6:30 p. m.

In the Grand Ball room of the La Salle Hotel a most enjoyable smoker was tendered the members and guests at which a Dutch lunch was served, interspersed with vaudeville numbers. Orchestral music enlivened the occasion.

Manufacturers of Mining Machinery and Supplies Have Notable Exhibit.

The conveniences which have become necessities in the industrial world above ground are rapidly being extended to equally important uses underground in mines. The electric lamp, the electric railroad and other machinery operated by electric power, the telephone, the acetylene lamp, etc., have become indispensable to efficient mining. It would be a difficult matter to imagine our large copper, gold, silver, coal or iron mines being worked on anything like their present scale with only the facilities available a century ago. Their operation would be physically and financially impossible on the tremendous scale of the present time. Every means available must be employed to increase output and decrease cost of production.

Seldom, if ever, does it come within the reach of the average operator, mine manager or superintendent to have the opportunity to see or know of every new device put upon the market that will increase the efficiencies of his operations. In the exhibits made by manufacturers of machinery and supplies at the nineteenth annual session of the American Mining Congress in Chicago, an unusual opportunity was afforded the mining man to get in touch with many new appliances as well as the standard products that have stood the test of time and will continue to do so for time to come.

Among the exhibitors were the following:

H. R. Ameline Prospecting Co., Core Drill Contractors.—Gave a drill demonstration in motion pictures, the first demonstration of its kind given.

American Mine Door Co., Canton, Ohio.—Automatic mine door, automatic mine switch, extension lever track switch, automatic electric switch, trolley wire splice, insulated trolley splice, solid feed wire splice, flexible cable splice, section insulators, trolley frogs, automatic signals.

Carbic Mfg. Co., Duluth, Minn.—Carbic portable welding outfit and flare lights.

Central Foundry Co., New York.—Universal cast iron pipe and fittings.

Edward Christman, Drilling Specialist, Massillon, Ohio.—Development of mineral land and water supply. Exhibited a miniature oil well drill in operation. Sample of cores were displayed.

R. & J. Dick, Ltd., Passaic, N. J.—"Dickbelt," the original Balata belt; Barry patent transmission equipment; tubular steel-split pulleys; semi-steel drop hangers, adjustable post hangers.

Draeger Oxygen Apparatus Co., Pittsburgh, Pa.—American-made oxygen breathing apparatus, for mines, and the small self-rescue apparatus for light engineering work; type B pulmotor; safety signs; electrically lighted bulletin boards, and a full line of safety-first supplies.

Electric Storage Battery Co., Chicago.—Submarine cell as used by the U. S. Navy; iron clad-oxide cells, as used on storage battery locomotives, iron clad-oxide cell cut away to show internal construction.

Fairmont Mining Machinery Co., Fairmont, Va.—Railroad car retarder, portable electric mine pump, steel mine ties, conveyors, car hauls, tipples, etc.

J. D. Fate Co., Plymouth, Ohio.—The Plymouth mine locomotive (gasoline type). A list of the company's installations in the mining industry was shown covering practically every branch of the industry in this and foreign countries.

Felt & Tarrant Mfg. Co., Chicago.—The controlled key comptometer, adding and calculating machines.

General Electric Co., Schenectady, N. Y.—Permissible miners' electric cap lamps, with several new and novel safety

features; new form H-2 incandescent headlight for mining locomotives, illustrating special features, such as the adjustable focussing device, parabolic glass reflector and spring suspension; line material devices, such as suspensions, clamps and roof attachments for mine haulage systems; mining machine and locomotive reel cables.

Goodman Mfg. Co., Chicago.—Storage battery and trolley type electric mining locomotives and electric coal-cutting machines (photos).

Haggard & Marcusson Co., Chicago.—Tiger steel bunks for housing men in bunk houses under sanitary and comfortable conditions.

Jeffrey Mfg. Co., Columbus, Ohio.—Photographs and literature on electric locomotives, crushers, conveyors, rotary drills, fans, truck loaders, etc.

Justrite Mfg. Co., Chicago.—Carbide lamps and lanterns for metal and coal mines, fire-prevention devices, non-explosive oil cans, automatic oil waste cans, chemical fire extinguishers, sanitary hospital pails, sanitary garbage cans.

Koering Process Cyanide Co., Detroit, Mich.—Literature covering the Koering method of extracting precious metals from their ores.

Link-Belt Co., Chicago.—Demonstrated by photos the handling and preparation of coal at the mine by Link-Belt machinery. Pictures were also shown of coal storage systems for both anthracite and bituminous coal; modern picking tables and loading booms; power-operated car dumps; the Ayres separator; portable wagon loaders, electric hoists and Link-Belt silent chain drives.

Macomber & Whyte Rope Co., Chicago.—Wire rope, wire rope fittings, Crosby clips, Monach car hitchings, lamp guards.

Miller, Earle & Miller, Inc., Distributors, Chicago.—Four wheel drive trucks and Troy truck trailers.

Monroe Calculating Machine Co., Chicago.—The Monroe calculating machine.

Morgan-Gardner Electric Co., Chicago.—Metal mines locomotives (photos).

Penacola Tar & Turpentine Co., Gulf Point, Fla.—Yellow long leaf pine, raw material and flotation oil.

John A. Roebling Sons Co., Trenton, N. J.—Wire rope and wire for every purpose.

Siebe, Gorman & Co., Ltd., London, Eng., represented by H. N. Elmer, Agent for North America and Mexico.—"Proto" self-contained oxygen breathing apparatus for mine rescue work; "Salvus" half-hour self-contained oxygen breathing apparatus for rescue work of short duration, especially ammonia fumes, chemical laboratories, etc.; flannel smoke helmet and respirator used by British army in combating gas attacks; helmet and mask with telephone for use of firemen; "ambalanza" oxide generator for first aid work; electric safety lamp; self contained diving suit used by Universal Film Co. in the production of "20,000 Leagues Under the Sea."

Stromberg-Carlson Telephone Mfg. Co., Rochester, N. Y., Chicago.—Exhibited the well-known Mine-a-Phone for underground work as well as other telephones used in connection with telephone systems for mines. Also mine signalling apparatus.

Sullivan Machinery Co., Chicago.—Diamond drills, diamond drill contracting coal drilling machines, chain coal cutting machines, air compressors and coal punching machines.

Tool Steel Gear & Pinion Co., Cincinnati, Ohio.—Tool steel hardened and toughened gears and pinions for mining locomotives and machines; also showing tool-steel pinion which has been in service five times as long as the average life of the untreated pinion in the same locomotive.

Vulcan Fuel Economy Co. (J. L. Simonds & Co.), Chicago.—Vulcan soot cleaner for water-tube and tubular boilers; Hays gas analyses instruments; Hays draft gages; Vulcan Lastite, an air-tight coating for boiler settings; Eclipse smoke indicator.

Miscellaneous Exhibits.

The Arizona Exhibit.—Representing the resources of the state, distributing a large variety of literature regarding the state, maps and samples from prominent mining districts, pictures and charts showing progress of the state, etc. Distributed badges of Mexican sombreros made of horsehair; also copper bricks, postcards, etc. Represented by Charles F. Willis, director Arizona State Bureau of Mines, and A. M. Heckman, secretary.

U. S. Bureau of Mines.—The U. S. Bureau of Mines is to be congratulated on its exceptionally fine educational exhibit of photographs and apparatus. The apparatus exhibited were only those which had stood a thorough test and were now in use by the bureau field men. Among the photographs shown were some 200 underground "safety" pictures recently taken by the bureau in co-operation with the Ellsworth Collieries Co. These vividly illustrate, in series of from two to five pictures, 50 of the most common accidents met with in soft coal mining. Each series typified a wrong practice, the accident resulting therefrom, and a right practice. Great interest was shown in these safety pictures.

There was also shown a set of pictures and diagrams illustrating rock dusting in coal mines and the application of rock

dust barriers. A mine accident statistical chart was also shown covering metal and coal mines.

The following apparatus was shown:

1. Fleuss-Proto oxygen mine-rescue apparatus.
2. Draeger (by-pass) oxygen mine-rescue apparatus.
3. Set of approved electric mine lamps.
4. Approved safety lamps.
5. Coal-sampling outfit.
6. Mine air sampling outfit.
7. Miner's first-aid cabinet.
8. Surgeon's emergency chest.
9. Burrell methane detector.
10. Canary bird for detecting carbon monoxide (white damp).
11. Fleuss one-half hour breathing apparatus.
12. Oxygen resuscitator.
13. Floor plan and elevation of new all-steel mine-rescue car.
14. Map showing all field activities.

The various Bureau exhibits attracted considerable attention and the various features were interestingly presented by Edward Steidle, mining engineer, in charge.

Mining Publications.—Coal Age, Engineering & Mining Journal, Denver Daily Mining & Financial Record, Mining & Engineering World.

Peculiar Engine Design.

When compressed air was brought in to be used in conjunction with steam in driving the hoisting engine at the Franklin Junior mine, in the Michigan copper country, considerable interest was aroused in connection with the unusual idea. The next step in such unusual practice is to be taken at the Ford Motor Co.'s plant. It consists of a twin tandem horizontal engine. One side is a gas engine with two cylinders in tandem and the other a tandem compound steam engine. The engines are connected to a shaft, on which is mounted a generator of 4000 kw. The gas engines have water-cooled cylinders 42 by 72 ins., and are of the 4-cycle double-acting type. The gas exhaust is utilized in a steam superheater on the steam main between the high-pressure and low-pressure cylinders of the steam engine. Some of the exhaust gas is passed through the jacket of the high-pressure cylinder to reduce heat loss. Finally the exhaust gases are utilized in the feed-water heaters for the boilers. This water has already passed through the cylinder jacket of the gas engine, and has thus been heated to about 180° F. before it enters the heater. The exhaust gas raises the temperature to about 250° F. for the feed. The gas-steam unit is designed to combine the economy of a gas engine under constant load with the reliability of a steam engine under varying load. A gas engine operates to best advantage under full and constant load. The general practice is to run the engine rather under-loaded. This produces wire-drawing of the gas through the valves and ports, which tends to cause a precipitation of matter. Such trouble does not occur with the engine running under full load. To avoid this with the combination unit the gas engine does not come into service until there is at least more than half load on the gas engine unit, so this engine will be normally under full load. The steam engine does all the governing and can meet fluctuations in the load. The only governing on the gas engine is to prevent excessive speed. In case of trouble with the gas side of the unit, the steam side can handle the full load by giving a late cut-off. No information as to the practicability of this design can be given, as the first units were installed late in 1915 and the plant as yet is not in operation.

Elevators receive very hard service and it will repay the mill man to make frequent and thorough inspection of these important machines.

In starting up a new plant, no part of the machinery requires more vigilant watching than the elevators.

Pumping by Compressed Air.

There are certain advantages in raising water by compressed air, where the conditions of service permit. These are enhanced if the system is so designed as to have no moving parts in contact with the water, other than the necessary check valves, so that sand, gravel and other solids may be raised along with the water without injury to the operative parts. Such a pumping system has been designed by Philip H. Shue of Denver, as shown in the diagram, Fig. 1.

The compressed air is admitted at (22) and passes up to the rocking valve (4) operated by the cam (5). As this valve tips back and forth on its axis, it admits air alternately behind the piston heads in the cylinder (15) so that the latter moves back and forth and

PUMPING BY COMPRESSED AIR.

oscillates the sprocket (18). This in turn oscillates valve (21), admitting air from (22), under pressure, through pipe (24) to chamber (27). This forces water up and out of pipe (44). At the same time valve (21) exhausts air through pipe (23) from the lower cylinder (32), allowing it to fill with water through the valves at the bottom.

Now when valve (21) is turned clockwise through a quarter circle, air is exhausted from chamber (27) and forced into (32), so that water rises from the latter and fills the former. Then the cycle is repeated.

As will be seen in Fig. 2, two pairs of chambers can be connected, water being carried up continuously from (A) to (B), (B) to (C) and (C) to (D).

Cupric chloride is sometimes preferred to all other reagents as an elimination of base metals by volatilization.

A 40-Ton Colorado Smelter.

Vulcan Mines & Smelter Co., Century building, Denver, has built and put in operation a 40-ton smelting plant at Vulcan, Gunnison county, Colorado. It is running on sulphide ore taken from Vulcan and Good Hope mines, on which this company has a lease and bond. The equipment consists of a cold-blast, pyritic furnace, designed by C. H. Mace, superintendent. The matte produced runs 51% iron, 23% sulphur, 15% copper, 4% zinc, 4 ozs. silver and 1 oz. gold per ton. By resmelting the matte a much higher grade product can be turned out, but thus far the

Mercury, flask, 75 lbs.....	37.00	200.00-300.00
Pebbles, French, ton f. o. b. New York	9.75	13.25
Pebbles, Danish, ton f. o. b. New York	13.00	15.00-16.00
Soda ash, 100 lbs.....	1.27	3.91
Sulphuric acid, 100 lbs.....	1.30	1.95
Zinc dust, lb.....	0.065	0.33-0.35

At Porcupine, which is about 100 miles northwest of Cobalt, still higher prices have prevailed and advances of from 8% to 427% of the cost of mill supplies is recorded.

Porcupine continues to be the principal gold-producing camp, and the output for 1915 was valued at \$7,580,766, as against \$5,203,229 for 1914. Cobalt is the main source of silver, having produced 234,000,000 ozs. since its discovery in 1904. The output for 1915

PYRITIC SMELTER OF VULCAN MINES & SMELTER CO., AT VULCAN, COLO.

matte in the form described has been marketed. Six cars of matte of this grade have been shipped.

All ore required for the smelting mixture is found in the mine, which is opened by a 700-ft. shaft. Lime is accessible in the vicinity. Coke for smelting and coal for steam power are shipped in. Robt. G. Ainsworth, Denver, is president of the company.

The Cobalt and Porcupine Districts, Ontario.

An unusual amount of interesting information is contained in the annual report of Arthur A. Cole, engineer for the Ontario Government railway, on the mining industry in northern Ontario. Much information and data on mining and metallurgy in the Cobalt and Porcupine districts is given. Ontario is now the largest gold and silver-producing province in Canada, yielding 44% of the gold and 87% of the silver. The increased cost of supplies during 1915 was partly compensated by the increased price of metals, but the greatest compensation came in the way of improvement in the work whereby costs per ton were materially reduced. The following comparative statement of the cost of milling supplies used at Cobalt will give an idea of the increase that has taken place:

Material.	Before the war.	March, 1916.
Aluminum dust, lb.....	\$0.34-\$0.38	\$0.75-\$0.90
Caustic soda, 100 lbs.....	1.30	7.50
Chrome-steel balls, 100 lbs.....	4.16	7.58
Cyanide—contract, lb.....	0.15	0.16
Cyanide—no contract, lb.....	0.15	0.20

was 23,653,713 ozs., a decrease from the previous year when the output was 25,162,841 ozs. The production of silver from Cobalt has constantly decreased since 1911, when the high point of 31,507,791 ozs. was reached. There were nine companies at Cobalt, each of which produced more than one million ounces of silver during 1915. Dividends and bonuses paid by Cobalt companies in 1915 amounted to \$4,523,415; the grand total since the discovery of the camp is \$57,614,202.

A number of Cobalt companies are now employing the flotation process. The largest plant is that of the Buffalo Co., which experimented first with a 50-ton plant of the Callow pneumatic type. A permanent plant of 600 tons capacity is now being erected for the treatment of 500 tons per day of accumulated tailings from water concentration and of 100 tons of mine rock. The fine-grinding equipment will consist of four 5 ft. 6 in. by 20 ft. tube-mills, and the flotation plant of four 2-compartment, triple-length Callow cells to be used as roughers and four standard 2-compartment cells as cleaners. The old cyanide plant will be used for dewatering flotation concentrate and for the cyanidation of flotation middling.

Any mine in which leasers can make a profit and pay royalty can be operated at profit by the company if the management understands its business.

An old rule that was a safe guide in developing mines was to follow the ore. This rule is as good now as it ever was.

What the Mining Companies are Doing

Cons. Interstate-Callahan, Idaho.

Operations of the company for the third quarter of 1916 are shown in the following report just issued:

Net value of shipments	\$655,031.04
Miscellaneous receipts	6,030.34
Total net value	\$661,064.38
Operating costs	247,369.39
Profit	\$413,694.99
Cost of improvements	7,968.47
Surplus for period	\$405,726.52

The principal features of the mining and milling operations during the period were as follows:

Tonnage mined	38,695
Tonnage milled	32,938
Average contents—	
Zinc, %	25.70
Silver, ozs. per ton	1.80
Lead, %	5.60
Shipped	
Zinc ore crude	3,297
Zinc concentrates	14,184
Lead ore crude	388
Lead concentrates	1,121
Total	18,990
Zinc, lbs.	3,329,970
Lead, lbs.	146,664
Total	17,451,243

Total mill recovery, %	\$5.70
Mill recovery on basis of metals paid for, %	\$2.90
Total zinc in zinc crude and zinc concentrates shipped, lbs.	16,868,836
Total lead in lead crude and lead concentrates shipped, lbs.	1,454,562
Cost of mining, per ton extracted	\$5.050
Cost of milling, per ton extracted	1.252
Cost of mining and milling, per ton extracted	6.302

Caledonia Mining Co., Idaho.

The Caledonia Mining Co. earned a net profit of \$296,390 during the quarter ended Sept. 30, according to the official report of Charles McKinnis, secretary-manager of the corporation. Total mining, milling and shipping costs were \$7,617 and the surplus at the end of the period was \$375,366. The increase in metal prices since the report was issued will add materially to the settlements for ore in transit, and the company will be able to continue dividend payments at the rate of 3 cts. a share, or \$78,150, for the remainder of the current year.

Development work is being carried on continuously in the Keating tunnel level in an effort to recover the faulted ore body, but so far without success. The work is being continued, however, and the territory in which it is believed the lost shoot will be found is to be thoroughly explored.

Detailed report of operations during the quarter follows:

Total dry tons shipped	4,865.72
Lbs. of lead	2,652,600
Ozs. of silver	350,421.83
Lbs. of copper	220,680.46
Total	\$172,502.61
Gross value	\$460,972.55
Freight and treatment	126,964.68
Net value of bullion	\$334,008.27
Mining cost	31,133.70
Milling cost	5,385.65
Shipping cost	1,098.64
Total operating cost	\$37,617.99
Profit available for dividends	\$296,390.28
Cash in banks, Sept. 30	\$275,533.10
Inventory, ore on hand	25,823.00
Due from smelters and ore in transit	89,142.19
Total	\$390,560.29
Less current bills	15,194.21
Surplus	\$375,366.08

Butte & Superior Co., Montana.

The Butte & Superior Co.'s report for the quarter ended Sept. 30 shows net operating profits of \$947,901, equivalent to \$3.27 per share, compared with \$7.56 a share in previous

quarter. In corresponding quarter in 1915 profits were \$2,560,327.

Comparison with 3 previous quarters follows:

	1916			1915
	Sept. 30.	June 30.	March 31.	Dec. 31.
Net value zinc concent.	\$1,731,670	\$2,879,568	\$4,337,412	\$3,614,570
Net value lead concent.	190,099	246,341	264,303	240,053
Miscellaneous income	14,757	22,772	21,427	18,265
Total	\$1,936,527	\$3,148,682	\$4,623,143	\$3,872,888
Operating costs	988,625	1,086,653	1,068,203	112,849
Net operating profits ..	\$947,901	\$2,062,029	\$3,551,940	\$2,760,039

Operating statistics for the past 4 quarters compare as follows:

	1916			1915
	Sept. 30.	June 30.	March 31.	Dec. 31.
Ore milled—tons	136,130	161,270	164,590	150,150
% zinc	15.55	15.970	15.692	16.66
Silver—ozs. (per ton) ..	6.60	6.7041	6.844	7.04
Zinc in concent.—lbs. ..	59,519,432	47,901,445	47,938,530	17,563,144
% zinc in concentrates ..	52.92	52.997	53.122	53.63
Silver—ozs. (per ton) ..	21.5	21.87	22.018	21.419
Mill recovery %	93.3	92.989	92.855	95.07
Mining cost per ton ...	\$4.94	\$4.4971	\$4.0341	\$3.537
Milling cost per ton ...	2.169	1.761	1.5763	1.59
Total cost per ton ...	\$7.10	6.2581	5.6104	5.128

The decrease in tonnage of ore treated during the quarter was due to an accident in the shaft in August, thereby causing the suspension of operations for 11 days. The increased cost in mining and milling is due to the smaller tonnage treated, the constantly increasing cost of supplies and the larger maintenance costs brought about through repairs to the Black Rock shaft. The grade of ore mined and concentrates produced was slightly less than for the previous quarter, but the recovery was somewhat better.

Development work on the 1700 and 1800 ft. levels continues to show ore bodies of normal size and grade as compared with those above. This with development above these levels gave a total addition to reserves of 185,903 tons, or about 50,000 tons above the amount of ore mined during the quarter.

The chief features of interest are the continued extensions of ore bodies to the east of the former workings.

The average price used in estimating returns on spelter for the quarter is 8.3441 cts. per pound.

After disbursement on Sept. 30 of \$6.25 dividend the company had net quick assets of approximately \$2,700,000.

Selma Mines Co., Utah.

A financial statement has been issued by the Selma Mines Co. covering operations to Sept. 8, 1916, as follows:

Assets—	
Mine claims	\$ 47,800.00
Mine buildings	2,354.00
Mine machinery, tools and equipment	7,033.23
Stable equipment	934.00
Mine development	25,956.91
Promotion and organization expenses	21,770.64
Notes receivable	1,200.00
Accounts receivable	442.09
Advanced expense money	32.50
Treasury stock	13,294.55
Utah Savings & Trust Co.—Cash in bank	125.18
Total assets	\$120,993.10
Capital and Liabilities—	
Capital stock	\$ 50,000.00
Donated working capital	17,608.35
Partial payments on stock	772.50
Employees' wages payable, cash	958.92
Employees' wages payable, stock	2,470.40
Sundry accounts payable	974.59
Suspense account	127.58
Sundry cash overpayments	38
Cash credit	67.92
Premiums on capital stock	7,810.97
Assessments on stock	22,618.56
Suspended surplus derived from stock forfeitures	17,582.91
Total capital and liabilities	\$120,993.10

Intermountain Co., Mont.

The financial statement of the Intermountain Copper Mining Co. for the 11 months ended Oct. 1, shows receipts of \$69,741.52 for ore shipped, \$12,232.15 due from smelter

and \$12,843.74 on hand. Other details of the statement shows:

Treasury stock	\$ 3,480.00
Salary of manager, advances, boarding house profit, road and poor tax	4,725.58
Mine labor and supplies	15,360.99
Mine supplies	4,314.62
Mill labor	4,799.60
Mill supplies	3,129.29
Railroad operation, labor and supplies	3,451.97
Office salary and supplies	669.67
Freight on ore	4,334.31
Treatment charges	6,767.85

Miscellaneous Company Notes.

Utah Copper will expend \$1,000,000 in enlarging its tailings dam and adding 1400 acres to its tailings ground. A portion of the town of Garfield, Utah, will be removed.

It is learned that banking and mining interests have acquired by purchase 250,000 shares Ray Hercules Mining Co. stock. Part of this purchase was on account of treasury of the company, which is provided with \$500,000 additional cash.

The Butte & Superior mill output for the first half of October showed a large increase over same period of September, indicating monthly mine production of 55,000 tons ore against 50,150 tons in September and 15,909 tons concentrates against 13,650 tons in September, 16,000,000 lbs. zinc against 14,496,000 previous month.

Calumet & Arizona's production for 1916 will eclipse all records with an output of close to 72,000,000 lbs. of copper, compared with 65,269,000 lbs. in 1915, and 52,668,000 lbs. in 1914. The Briggs shaft mine at three new lower levels has opened up rich ore, while Cole and Junction shaft mines are both in new sulphide ore running better than 4%.

Earnings of the Ray Con. Copper Co. for 1916 will approximate \$12,000,000 net, equal to about \$8 a share. An ultimate capacity for producing about 100,000,000 and 120,000,000 lbs. of copper per annum has been outlined for the Ray property, and it is largely with this object in view that the management has built up a strong cash reserve for mine development and construction.

For the quarter ended Sept. 30 the American Zinc, Lead & Smelting Co. earned net profits of \$1,713,000. In the same period the Granby Co., now an integral part of the American Co., earned \$725,000, or a total of \$2,438,000. These figures compare with profit for the first 6 months ended June 30 of \$3,642,391, making a total net for the first 9 months of \$6,080,391. At the present time the company is earning at the rate of better than \$800,000 a month.

On Dec. 1 directors of the Utah Copper Co. will meet for dividend action. The last dividend was \$1.50 and \$1.50 extra. Such is the strength of the company's cash position, and so large have been the earnings resulting from 25-ct. copper, that a further increase is assured. The company has been expanding its output very rapidly, and, apart from its 51% interest in Nevada Con., the Utah Copper property alone has gotten its output up to a basis of 240,000,000 lbs. per annum.

The plan, which was duly adopted at the Seattle meeting of the Mother Lode of Alaska, provided for the issuance of \$1,000,000 of 10-year convertible 6% first mortgage gold bonds, an increase of the capitalization from \$5,000,000 to \$7,500,000, and the reduction of the number of shares from 5,000,000 of a par value of \$1 to 750,000 shares of a par value of \$10. Present stockholders will receive one share of the new stock in exchange for 10 shares of the old. The bonds will be dated October, 1916, and may be converted any time before maturity into stock at par, and are redeemable at any interest day after 3 years at 110 and accrued interest. From the proceeds from the sale of the bonds \$100,000 will be spent in opening up the mine for steady production, \$300,000 for a 100-ton concentrator, \$50,000 for a hydroelectric plant and \$50,000 for a wagon road and motor truck equipment. The balance will be reserved for working capital. Of the new stock, 100,000 shares are to be reserved

for bond conversion and 150,000 shares are to be held as a reserve in the treasury.

The Nevada Douglas Con. Copper Co. has issued its report for the quarter ending June 30. It shows that the total receipts were \$197,524. Of this amount \$105,936 was received from the shipment of ore and \$88,936 came from assessments, and all of which was expended. For the half year to June 30 the company earned \$11,044 net after all charges. The balance sheet as of June 30 shows a profit and loss surplus of \$328,685. Other statistics show that the ore averaged 12.34 per cent copper and that the company received an average price of 24.81 cts. per pound.

By the end of next year the Chino Copper Co. will be in position to produce copper at the rate of more than 100,000,000 lbs. of copper per annum, provided plans for increasing capacity have been completed on schedule. Two new units will be added to the Chino mill, and with their completion and operation, output should swell to at least 10,000,000 lbs. In the meantime the pace set by Chino during the month of September—7,300,000 lbs.—should be at least maintained and probably increased slightly, so that the company may be regarded for the immediate future as a 90,000,000 lbs. copper producer.

The improvement in the Boston & Corbin Mining Co. affairs, brought about by changes in the mill, and the addition of flotation, is illustrated by the comparison of tonnage treated and copper produced in the first half of October, as compared with August and September. The mill treated 2808 tons of ore in August, 2695 tons in September and 1429 tons the first 15 days in October. The copper product in August was 49,815 lbs., in September 53,622 lbs., and 32,000 lbs. for the first half of October. The silver product for these three periods was 2723 ozs., 3570 ozs., and 2117 ozs. In other words, on about the same tonnage the metallic products have increased over 28%.

The principal by-product of Nipissing Mines Co. which has closed an important contract for the handling of by-products, is cobalt, used extensively in manufacture of chrome nickel steel. At present there is a record-breaking demand for chrome nickel steel for automobile parts, shells and steel rails. Of two new veins recently discovered by Nipissing, one is estimated to contain 1,000,000 ozs. of silver, the second to run 1500 ozs. to the ton. This vein extends for 3000 ft. in the company's property. With silver selling at approximately 72 cts. an ounce the company is operating plant at capacity. It continues to pay quarterly dividends of 5% on the \$6,000,000 stock, and last quarter paid an extra 5%.

The American Smelting & Refining Co. will double the capacity of its tin smelter and refinery at Perth Amboy. As originally laid out, the plant had a capacity for 1000 tons of electrolytic tin a month, but units erected had an estimated capacity of only 500 tons a month. In operation, output has been found a little more than 300 tons a month, so the plant will be enlarged to size originally planned in order to increase output of tin. The additional units are expected to be ready in about 6 months. Expansion is largely on the refinery end and there is great difficulty in securing delivery of necessary electrical apparatus. The company will also expend \$5,000,000 to enlarge the Murray and Garfield plants. All the men that can possibly be employed to make alterations are engaged and the capacities of plants will be raised soon.

There was produced by the Chile Copper Co. during the first half of this year a total of 19,724,385 lbs. of copper. These figures are the first of their kind to be published concerning the company. It has been decided by the management is issue monthly reports of production hereafter. In carrying out the proposed plan for enlargement of the plant new financing will probably have to be arranged. No decision has actually been reached as to the form of new securities to issue, although \$10,000,000 has been mentioned as the amount to be raised. Up to the end of last August there had been spent on construction and equipment \$13,000,000, since which time no financial statement has been made public. The company has outstanding \$95,000,000 capital stock, and \$15,000,000 convertible 10-year 7% bonds. The floating debt last August was about \$5,000,000.

The Nineteenth Session of the American Mining Congress.

The Mining and Engineering World prints in this issue the stenographic report of the proceedings of the Nineteenth Annual Convention of the American Mining Congress, held in Chicago last week. The resolutions, passed after a most thorough thrashing out of the conflicting views of many minds, are an epitome of the mining demands of the country, the common ground on which all are agreed, and a consensus which the legislators of states and of the nation must heed if there is to be any real administrative helpfulness for this, the second great industry of the country. It was fortunate that the mining men present were able, in the confusion incident to an interminable program, to do so much.

But as always there is a fly in the ointment, and the Mining and Engineering World feels it is performing only its duty in pointing out to the mining men of the nation the rocks upon which the Congress is likely to end its long period of usefulness.

Criticism unless it is constructive is futile, and this article is written solely for the purpose of building up, or rather of repairing, than of tearing down.

First and foremost permit us to say that the American Mining Congress is assuming more and more the functions which are so ably performed by the national technical societies, the Institute of Mining Engineers and kindred organizations. As a matter of fact the preponderance of membership in the Congress is of mine owners and operators who have been coming to the Congress not for technical instruction, but rather to exchange views on practical mine betterments, on the possibilities of getting together for effective business co-operation, and more than all for the purpose of working hand in hand to avert destructive and to invite constructive legislation.

While topics along these lines were on the program they were only casually discussed and were in every instance rushed through to make way for papers and discussions of a purely technical nature. The entire time of the Congress might well have been devoted to five or six business-building topics instead of to forty or fifty papers on widely varying subjects, not one of which was gone into with any thoroughness. It was a case of "confusion worse confounded" to busy men whose minds run along the channels of pure practical industrial up-building.

But this duplication of effort is not confined to the programs. It has crept into the very life of the Congress. Here, for instance, is an illustration which merits serious consideration by the men who have the real interests of the Congress at heart. The United States Government is expending vast sums of money annually in properly exploiting the work of its bureaus. For the departments of Geology and of Mines there is published weekly through excellently-managed pub-

licity departments practically every piece of information that is of value to the oil, the coal and the metal mining men of the country. While much of this is published, at least in summary form, in the leading mining and engineering journals of the country, it is possible for any man interested to secure, free of all charge, the weekly contributions of the bureaus.

With these facilities in mind the American Mining Congress is spending a large part of its income in issuing an expensive journal, which can only mean loss and waste, and whose sole purpose is to republish what the bureaus and engineering journals are doing so well.

As far as its own propaganda is concerned there is not a class paper in the country, published along its lines, which is not giving without cost and with the utmost liberality as to space, whatever the American Mining Congress issues in the way of up-building and constructive publicity.

It was the most natural thing in the world for the Congress to swish around in search of new purposes after it had so ably aided in establishing the U. S. Bureau of Mines. And yet its new purposes lie clearly before it. For there is a real need for the organization in getting mining men together so that they may find a common ground on which by co-operative action they can make mining safer, make it more profitable, and avert disastrous legislation.

It is simply a case of "stick to your last, shoemaker."

Copper Prices in the Lake Superior Copper Region.

The average price for Lake Superior copper during the year 1916 will not net the mines of this district 25 cts. In fact the average will likely be closer to 24 than to 25 cts., unless a few large sales of spot copper is made at 36 or 38 cts. during November or December. Any mine that can show an average price for its metal for 1916 better than 26 cts. will be over the average for the district.

It must be remembered that a full year ago a large number of the mines of the Lake Superior district contracted for their entire output away long into 1916—until May and June—in many cases, at approximately 21 cts. It was good business at the time. Later they contracted for the remainder of the year at 27 and 28 cts. for the bulk of the product. Of course the domestic sales averaged somewhere in between 21 and 28 and 29 cts. And now those that have been able to turn out more copper than their contracts called for are getting 33, 34 and even higher bids for their ready-to-ship copper.

Considering earnings of Lake Superior copper shares it likewise must be remembered that contracts already have been made at 27, 28 and 29 cts. for the bulk of the copper from the mines of this district for January, February and even as far away as May delivery in 1917. The present top prices for the metal

are for small lots, and do not represent any considerable tonnage, although they do indicate the advantages that some of the smaller, independent producers, may be able to secure in the sale of their metal.

Relative to the possibility of the ending of the war in Europe and its effect on the price of copper, it is explained that there is little likelihood of any European nation cancelling any present contracts for copper, for the reason that each would want to be fully prepared for any eventuality, and would desire to maintain its stock of war munitions up to the limit, to say nothing of trade demands and the re-entrance of Germany to the copper metal market; Germany took 40% of the Lake Superior product for regular trade requirements before the war broke out. Even if contracts should be broken by the war in Europe provisions are made so that little loss could accrue to the mining companies.

It often happens that one of the most expensive items on the bill for equipping a new mine, or that of replacing the old machinery with something better is that of hauling the ponderous pieces of steel and iron from the railroad to the property. The sites for mines are not selected by any means; they must be wherever the ledges are. Frequently this is an isolated spot, and nearly always in a mountainous country, a long distance from a railroad or main traveled highway. A certain amount of expense, hard labor and annoyance must be suffered to get the machinery in place, but a little intelligence along with the hard work will often reduce the expense bill very materially.

In view of the remarkable progress that has been made in mining in the United States in the last few years, it has become apparent that the industry, though ever attractive to the business man, has assumed proportions that entitle it to more than a speculative interest. Though great strides have been made in mining and in the manufacture of mining machinery, it is but a forerunner of the marked advances that bid fair to be accomplished in the next few years. To those conversant with the situation the outlook is contemplated with the keenest satisfaction.

City officials of Wardner, Idaho, have granted a lease permitting mining beneath the streets, alleys and other property belonging to that city. The lease is to run for a period of 25 years and calls for the payment of 5% of the gross proceeds of all ores extracted from the premises included in the lease. A shaft is to be sunk to a depth of 1000 ft. below the Main street level and an effort made from that depth to reach the main leads crossing between the Bunker Hill and Stewart veins to the south of the Osburn fault.

The interests of good mining are not always served by the finding of rich ore. True progress in the art is more apt to be recorded in the low-grade mines, especially those containing copper, lead and zinc, where small economies may make the difference between profit and loss, and so it comes that the best practice and the most modern investigations may be found in our base metal mines.

PERSONAL.

William L. Creden has resigned as manager of the Utah Apex properties in Utah.

C. M. Weld, consulting engineer, New York, has left on a 2 weeks' trip to Cuba.

G. W. Evans, mining engineer, Seattle, Wash., has returned from a trip to Alaska.

F. M. Wichman, recently operating property near Nevada City, Calif., is in Montclair, N. J.

V. H. McNutt, geologist and mining engineer, Tulsa Okla., has returned from New York.

C. O. Lindberg, consulting mining engineer, New York, is in Chicago on professional duties.

F. Lynwood Garrison, consulting engineer, Philadelphia, Pa., is now back from a trip to Brazil.

Eli Cinde has been appointed superintendent of the New Golden West Mines Co., Deadwood, S. D.

Ben Wilson, manager of the Montana-Illinois Mining Co., Butte, Mont., is on a home visit in Iowa.

H. G. Ferguson of the U. S. Geological Survey, is examining areas in the Mogollon district, New Mexico.

E. V. Daveler, metallurgical superintendent of the Alaska Gold Mines Co., Thane, Alaska, is in San Francisco.

L. C. Hodson, professor of mining and metallurgy, Iowa State University, Ames, Iowa, is visiting in Chicago.

Victor C. Alderson, ex-president of the Colorado School of Mines, has arrived in San Francisco from New York.

Harry J. Sheafe, mining engineer, Los Angeles, Cal., has recently been in Dulzura, Calif., near the Mexican border.

John F. Martin is now superintendent of the La Luz & Los Angeles Co., in the Prinzapolka district, Nicaragua.

E. A. Suverkrop, Jr., mining engineer with the Chile Exploration Co., has returned to Chuquicamata, Chile, from a visit to New York.

William C. Madge, mechanical and metallurgical engineer, London, E. C., England, is now in the United States from Siberia and will leave for London soon.

J. L. Bruce, general manager of the Butte & Superior Mining Co., Butte, Mont., has returned from a trip of inspection of the American Zinc Co. properties in Missouri.

M. H. Sullivan, assistant superintendent of the Consolidated smelter, Trail, B. C., has resigned to accept the position of smelter superintendent for the Bunker Hill & Sullivan Co., Kellogg, Idaho.

J. A. Quick, Frank Breeze and Paul Greyer of the Columbia Mines Co., Atlin, B. C., have left for the winter, via Skagway, for London, Ont.; Vancouver, B. C., and Cincinnati, Ohio, respectively.

Henry D. Wilbauer, William S. Pritchard and S. Gregory, all of New York, were in Butte, Mont., last week to look into mining conditions. All three men are mining capitalists from Gotham and all are interested in that camp.

OBITUARY.

Edward Thomas Hendee, secretary of Jos. T. Ryerson & Co., died Nov. 12, 1916, at Minneapolis, Minn., at the age of 36. Mr. Hendee graduated from the New York University in 1900 with the degree of B. S., afterwards receiving the degrees of M. E. and M. S. He received the degree of Sc. D. at Columbia University in 1901. From 1901

to 1902 he was assistant professor of mechanical engineering at New York University. In 1902 he became associated with Joseph T. Ryerson & Son of Chicago as advertising manager. He built up and became manager of the machinery department. He was made assistant to the president in January, 1911. In 1913 he assumed charge of the railway supply department of the firm. In 1913 he was elected secretary and continued so to his death.

Emil Storer, secretary-treasurer of the South Hecla Mining Co., Cottonwood, Utah, died on Nov. 4, 1916, in Salt Lake City. His death, which was caused from infection of the eyes, was both unusual and sudden. Mr. Storer came to Utah from Indianapolis, Ind., in 1898 and was 72 years of age at the time of his death.

SCHOOLS AND SOCIETIES.

Michigan College of Mines.—The Students' Organization of the Michigan College of Mines has recently been affiliated with the American Institute of Mining Engineers. In behalf of this an address is to be made to the organization on the benefits, usefulness and purposes of the American Institute of Mining Engineers.

American Institute of Mining Engineers.—The sixth annual meeting of the Columbia section of the Institute will be held in the Spokane Hotel, Spokane, Wash., on Nov. 25. The program will be as follows: Address of Retiring Chairman, Stanley A. Easton; report of Secretary-Treasurer L. K. Armstrong; installation of newly elected officers and election of the same. A discussion of U. S. Mining Laws, Flotation, Land Classification, State and National Co-Operation, etc.

NEW PUBLICATIONS.

A Reconnaissance of the Cottonwood-American Fork Mining Region, Utah. By B. S. Butler and G. F. Loughlin. Washington, D. C., U. S. Geological Survey. Bulletin 620-I; pp. 62.

The bulletin is an advance report on the district and will later be included in a report on the ore deposits of the entire state. It is based on a reconnaissance which is insufficient to include the more detailed points and is a general description of the main features with respect to stratigraphy, structure, ore deposition and general geology.

Antimony Deposits of Alaska. By Alfred H. Brooks. Washington, D. C., U. S. Geological Survey. Bulletin 649; pp. 67; illustrated.

Though there are 67 localities in Alaska which produce some antimony or at least in which it is present, Fairbanks, according to the prominence given the various localities in this publication, seems to be the one of most importance. The field examinations were limited to this and the Iditarod districts, though the other districts are also described, the data having been obtained from the notes and writings of other authors.

Gold, Silver, Copper, Lead and Zinc in California and Oregon in 1915. By Charles G. Yale. Washington, D. C., U. S. Geological Survey. Mineral Resources of U. S. I:10; pp. 51.

Both of the states are reviewed separately, the outline of each report being identical. The general metal production of the state is first reviewed by the different metals and followed by a review for the year of the mining and metallurgical industry of the state in so far as it is affiliated with the metals mentioned. Tables showing various productions are given and separate reviews of mine and metallurgical plants are then made by counties.

Progress Made in the Manufacturing Industries

Morse Bros. Make a Large Purchase.

The entire assets of the United States Reduction & Refining Co., recently sold by the U. S. Court to the Golden Cycle Mining Co., have been purchased from them by the Morse Bros. Machinery & Supply Co. of Denver, who will dismantle the mills. The Standard plant at Colorado City was a 1000-ton daily capacity chlorination, concentration and cyanide plant, crushing being done in rolls and tube mills; 1500 hp. in individual induction motors drove the machinery. The chlorine gas used in the process was made at the plant. The Union plant at Florence was a 700-ton chlorination, concentration plant, crushing being done by rolls. Electricity generated at the plant with steam furnished the current for the motors used there. The U. S. Smelting Co. at Canon City was a smelter making "zinc lead white" from zinc sulphide ores. The plant had a daily capacity of 700 tons. The Bimetallic plant is a modern cyanide plant of 500-tons capacity for treating tailings from the old Bimetallic mill destroyed by fire several years ago. The dismantling of these plants marks the passing of chlorination treatment of Cripple Creek ores, and is the answer to the controversy waged 10 years ago as to the relative merits of the two treatments. The U. S. Reduction & Refining Co. had a capital stock of \$6,000,000 common, \$4,000,000 preferred and a bond issue of \$2,650,000. This is the largest purchase of milling plants ever made in the west, and adds quantities of nearly every kind of machinery to the Morse Bros. stock. In these plants there is 15,000 tons of machinery, 5000 tons of structural steel and buildings, 2000 tons of pipe, 300 tons of lead, 45 tons copper wire, 12,000,000 ft. of lumber, 10,000 squares corrugated iron. Over 1500 acres of land with water rights was also included.

TRADE PUBLICATIONS.

Packing for Air Pumps and Compressors. The United States Metallic Packing Co., Philadelphia. Circular; illustrated.

In a sectional view the nature of these packing rings is shown. A brief description gives information on the installation and proper care of packing rings.

Pumping and Dredging Machinery. Byron Jackson Iron Works, San Francisco. Bulletins; illustrated.

Information of value in the design and practical installation and operation of systems is given in each bulletin, each of which takes up the description of different kinds of pumps. Descriptions of the different pumps, their construction and information as to the work for which they are best adapted is given, with tables of details regarding the capacity and dimensions of each.

Acetylene Gas Tips and Burners. American Lava Co., Chattanooga, Tenn. Catalog No. 19; pp 23; illustrated.

The general text of the catalog is written in French, Spanish and English with a glossary of terms used in the listing of the different types of burners as this portion of the catalog is entirely in English. The list gives an illustration of each burner, a description in few words and the price of the burners. Since acetylene is becoming so popular for illumination underground and in remote sections this catalog will be found of considerable interest.

Water Purification with Sulphate of Iron. American Steel & Wire Co., Chicago. Manual; pp 152; illustrated.

This manual "System of Water Purification" is purely a text on this method of purifying water being written in as brief a form as the subject will allow. A general discussion of the necessity of water purification in certain instances is brought out. Formulas and other tabulated data of practical use is given in describing the system and its

installation in plants. Various tables of value to users of purification systems are given and drawings and illustrations of plants are reproduced.

Gandy Belting. The Gandy Belting Co., Baltimore, Md. Booklets and Price List.

Different features of this belting are brought out through experiences of the company and letters of recommendation from users of the belting. Rules for figuring the size and class of belting needed in various instances are given as also is a price list. The belt is made from stitched cotton duck which is treated with oil and paint.

High Vacuum Pumps. Eimer & Amend, New York. Bulletin No. 5; pp. 12; illustrated.

Three different types of pumps are included. A general talk on the May-Nelson high vacuum pumps in which is embodied the later features and conveniences of the pump. An evacuation-time curve is reproduced and there is a separate treatise on the principles of the pump, its operation and installation. Specifications and prices are given for each of the three types.

Overhead Carrying Devices. New Jersey Foundry & Machine Co., New York. Catalog 88; pp. 48; illustrated.

Many of the devices described are of the well known mono-rail type which is used around smelters and mine plants. Hoists for the handling of equipment in the shops and grab buckets for moving materials around the plant are among some of the devices considered which operate on this mono-rail system. Traveling cranes and similar devices are listed, as is also other sundry equipment used in connection with this type of carrying.

Scales, Trucks, Mine Cars, Wheelbarrows, Concrete Mixers, Etc. The Standard Scale & Supply Co., Pittsburgh, Pa. Catalogs A210 and D95A; pp. 192 and 130; illustrated.

Prices, brief descriptions, and illustrations of each piece of equipment are given. The equipment included consists of trucks of all kinds for use about the plant, at the smelter and mine; wheelbarrows and carts of particular use about the mill and smelter, steel scrapers for excavation work; mine cars, coal chutes, screens, concrete mixers and equipment, etc. Catalog A210 is confined to the listing of scales for various kinds of use, and including the smaller platform scales of portable type as well as the larger stationary platform scales.

INDUSTRIAL AND TRADE NOTES.

F. W. O'Neil, who recently resigned from the Nordberg Mfg. Co. to accept a position with the Ingersoll-Rand Co., New York, has been appointed assistant general manager of sales.

E. W. Petter, chairman of Petters, Limited, Yeovil and London, England, is in this country making arrangements to organize an American company to build the Petter semi-Diesel crude oil engine, which is widely and favorably known in mining districts in all parts of the world, except the United States, although several engines have been successfully operated in Alaska for over 2 years.

F. B. Gleason, formerly in charge of the Western Electric Co.'s business in the Far East, with headquarters at Tokio, Japan, has been appointed manager of the Southern district with headquarters at Atlanta, Ga. He will succeed E. J. Wallis, who, on Jan. 1, will take up his new work as manager of the Pacific Coast district, with headquarters at San Francisco. Mr. Wallis will succeed F. H. Leggett, who, after 3 years on the coast, returns to the company's executive offices, New York.

Late News From the World's Mining Camps

Editorial and Special Correspondence.

ALASKA.

Carcross, Y. T.

With the addition of two more shipments to the smelters at Trail and Anyox, British Columbia, the Venus mine has shipped 500 tons since the resuming of operations this season. A launch has been used to convey the ore to this city, and when the lake freezes it will be hauled by horses.

Twenty-four men are now being employed on the Montana group, and ice has been cleared from the shaft down to the 180 level.

Fairbanks.

The Bureau of Mines has made a final decision on establishing an experimental station here which will be the first and only one in Alaska. John A. Davis, who is now in Alaska, will have charge. He will leave shortly and return in the spring to commence the actual establishment of the station.

Cordova.

In the upper Copper River valley good deposits of mineral other than copper have recently been uncovered, it is rumored. The new find is a ledge 60 ft. wide which contains silver-lead ore, and located in a lime-greenstone contact with the lime formation for the footwall and greenstone the hanging wall. The locators intend to start a tunnel in the spring and bring out a trial shipment for the smelter as soon as possible.

Anvick.

McGrath and associates are working the Marshall placer ground on the lower Yukon. The ground is somewhat expensive to work but is yielding \$3 per foot. In a recent cleanup \$44,000 was said to be taken, and the operators expect as much again before closing for the season. About 400 men are in the district.

Taku Harbor.

A mill, similar in design to that at the Alaska-Gastineau, is to be installed at the Engineer mine. James Alexander, general manager, has left for Denver, Colo., where he will purchase a 100-ton ball-mill for his plant.

Anchorage.

The work on the new railroad is progressing and W. C. Edes of the Alaska Engineering Commission states that 59 miles of track have been laid from Anchorage. With the 71 miles of the old Alaska Northern Railway that is now in operation to Kern Creek, there have been completed 130 miles of the 470 that will connect Seward and Fairbanks. The track so far laid from Anchorage consists of 6 miles south toward Seward; 38 miles of main line north to Fairbanks, and 15 miles on the Matanuska branch into the coal fields. The right of way has been cleared from Potter Creek on Turnagain Arm to Kings River in the Matanuska coal field, a distance of 77 miles and on the main line from Matanuska to the Little Susitna river. Rail will be laid this fall as far as Kings River on the Matanuska branch, 62 miles from Anchorage, and to Wassilla on the main line, 15 miles from Matanuska. On the main line in Susitna Valley, between Montana Creek and Indian river, a distance of 55 miles, the right of way is 70% cleared and a number of grading contracts have been let. Grading of the right of way will proceed in this section from Talkeetna to Willow Creek, and north to Broad Pass. At Willow Creek it will connect with the work under the Matanuska district, and at Broad Pass with the work from the Nenana division. Rail will be laid in the near future as far as Potter Creek, which is 15 miles southeast of Anchorage on Turnagain Arm, and from which point the rock work on Turnagain Arm will be attacked during the winter.

ARIZONA.

Miami.

In the extension of the Inspiration concentrator, which will soon be completed, items of interest in crushing will be brought out, it is said, in the process being installed. The flow will probably be identical with that in the main plant. It is understood that in the grinding equipment, Hardinge ball mills will be run in competition with Marcy ball mills. Heretofore the Marcy mill has shown the ability to reduce rock from 3-in. size such that only 2% would remain on a #40-mesh screen in a single stage. The Hardinge mill in this plant will probably perform its work by two mills in series, one mill reducing to half the desired size, and passing it to the next mill for finishing.

Oatman.

During the past 10 days there have been notable developments in two Oatman properties, and a third is now coming into attention. The Nellie Co., operating in the Black Range section of the district, sent its crosscut on the 350 level through more than 35 ft. of vein matter, of which 25 ft. was ore averaging better than \$12 gold. Measured at right angles the ore shoot is about 17 ft. in width. Drifting has now started on the ore shoot, in both directions. The United Northern, to the north of the United Eastern, something over a mile, has on the 400 level crosscut a vein of 53 ft. in width. About 16 ft. is good mill-grade ore. The vein is somewhat faulted and broken at this point, and drifting is now being started in both directions. This is one of the largest veins opened in the district at this depth. The entire vein is strongly mineralized. The shaft will be carried down 600 ft. for lateral work at greater depth.

The third property is the Iowa, which at a depth of 400 ft. has entered its vein from the foot-wall side, and is showing some 8 ft. of milling ore. Drifting to the west is in progress and shows that the vein is widening and values increasing. Mining men regard the showing as pointing to important results within a short time.

The Carter has been refinanced, according to official announcement, 350,000 shares having been sold for 19½ cts. per share, this money going into the treasury. The sale agreement calls for continuous operation for 6 months. The interests making the purchase control two other near-by properties and are planning the erection of a 200-ton mill to handle the ores from the Carter and other properties. The Carter has quite a large tonnage of fine milling ore blocked out on three levels, down to 350 ft. Work at greater depth will now be prosecuted.

The Fessenden officials state that negotiations with the Pittsburg syndicate for control of the company are still in progress. Statement that work will be resumed shortly, with ample finances back of the company is significant. It is rumored that the deal has actually been agreed upon, but that official verification will not be made until actual stock transfers have been made.

The Lucky Boy, after some delay, resumed operation last week. The operators believe that they are within 60 days of pay ore. During their period of inactivity, development in surrounding territory has been of much assistance in giving clues to the geological conditions to be found in the Lucky Boy.

The Ivanhoe has its new compressor and pumping plant installed, and as soon as the mine can be pumped out will resume development work on the 500 level. When the water drove the miners out a full face of ore had just been encountered. For some time a drift had been driving along

a spur vein, and the inflow of water appears to have started when the main vein was encountered.

The Adams, with its shaft down 400 ft. is now cutting a station, and next week will be engaged in driving a crosscut to its vein. This property has a good surface showing, and is well financed.

Prescott.

The Commercial mine in Copper Basin, owned by the Phelps-Dodge interests, is shipping from 80 to 100 tons of copper ore daily to smelter, and could increase the tonnage considerably were it not for the fact that smelting facilities are not keeping pace with the output of Arizona's mines, either in this or other mining counties of the state. Adjoining the Commercial mine is the property of the Loma Prieta Co., where a body of ore having a general average grade of 2½% copper is being developed. A small tonnage of sorted ore on the dump samples about 15% copper. The property is to be equipped with a modern plant of machinery and developed at depth. The present depth of the shaft is 155 ft., and it is in a solid body of chalcopryite ore from the 80-ft. point down.

The property of the Copper Hill Co., a corporation dominated by E. S. Clark and John J. Jackson, of Prescott, is another Copper Basin property for which a future is predicted. Next to the Commercial mine, the Copper Hill has been developed to a greater extent than any mine in the basin. Commercial ore is exposed on three levels and has been stoped to some extent above each. Several shipments have been made at a good profit, and the mine is in general in excellent shape for future production. Other properties in Copper Basin having a copper ore showing above average are the Schuber, Blickenstaff, McBride-McNulty, John H. Robinson and Lucky Five.

Mineral conditions continue to improve as development work progresses on the 8th level of the Harqua Hala Bonanza mine, a Yuma county property in which H. William Stevens and other Prescott mining men are heavily interested. Hitherto worked as a gold proposition solely, it now appears probable the mine will in due course come to the fore as a copper proposition. Sulphide ore carrying 5.8% copper was opened several months ago on the 8th level in connection with a large body of oxidized ore carrying high values in gold.

Jerome.

Early December will record the calling of the shares of the Boston and Jerome Copper Co. on the New York Curb. The Boston and Jerome is one of the early-day mining propositions of the Verde district. It consists of 12 claims, a number of which are patented, and is located in the recognized productive area of the Jerome copper belt. It lies 2 miles south of Jerome and adjoins the Verde Central Copper Co. on the west. Considerable development work was done in past years. A lack of funds, however, at that time forced suspension of operations. From then until recently the property remained dormant. Reorganization of the company and a refinancing of its treasury has been perfected through the efforts of S. F. Balentine, of Jerome, who has interested in the proposition several well known mining men of Arizona and a number of wealthy Eastern parties.

Before the close of the current month the shares of the United Verde Con. Co. will be listed and called on the New York Curb. Representatives of the company are now in New York for that purpose, and it is said the stock will open at \$1 per share.

Diamond drilling operations are being prosecuted on the company's United Verde Junior group about 1½ miles south of Jerome, and are to be supplemented in the near future by operations on the company's Mahurin group in the Copper Canyon country. The former is traversed by a strong vein outcrop and is considered promising, while the latter offers ore yielding possibilities similar to those of the copper-porphry deposits of the Ray country.

At the annual meeting of the Venture Hill Co. held a few days ago in Prescott, W. R. Uber, Ed Kiehl, C. T. Jolly, Phil Pecharich and Ed Shumate were elected directors for the ensuing year. The officers will be: Ed Shumate, of Prescott, president-treasurer; C. T. Jolly, of Clarkdale, vice-president; W. R. Uber, of Los Angeles, secretary, and

Ed Kiehl, of Prescott, assistant secretary. The annual report of the company, soon to be issued, will show 437,000 shares of treasury stock, and a treasury fund of \$14,000. The company's property carries a good copper showing, and is being developed under the supervision of John S. Riley, formerly of the United Verde Extension.

Operations are being prosecuted in conjunction with the Verde Apex Co. on a 50-50 expense sharing basis. A force of 25 men is employed in erecting the camp buildings and grading a site for the joint 3-compartment shaft. As soon as the cook house and sleeping quarters are completed the working force is to be doubled. The Venture Hill tunnel has been driven to the line of the Verde Apex ground and a crosscut is now being driven therefrom to the site of the shaft. The plant of machinery, ordered jointly by the Venture Hill and Verde Apex, is en route, and the cement foundations on which it will set are nearing completion.

CALIFORNIA.

Julien.

Friday Copper Mines Co., controlled by W. E. Sterne and L. A. Ellis, San Diego, is opening important deposits of nickel-iron sulphide ore in what was originally started as a copper mine. The ore was oxidized and leached near the surface, but at 100 to 200 ft. depth it is found to be a sulphide. The ore bodies occur in irregular deposits in igneous rock. Samples considered typical of the ore exposed in the workings contained the following, according to assays made: Pyrrhotite, 43.99%; silica, 3.08%; sulphur, 35.11%; arsenic, 0.15%; nickel, 4.12%; copper, 0.93%. Some assays, in addition to the above metals, showed the presence of cobalt and zinc. Two drifts have been run in ore from a 200-ft. shaft, one drift being 50 ft. below the other. This work showed a 14-ft. width of ore. The company is making an effort to develop the property as extensively as possible and block out the ore before attempting to find a market for it. Julien district is 60 miles east of San Diego.

Encinitas.

Encinitas Copper Co. is operating 8 miles east of Encinitas, W. H. McKinnon being superintendent. The mine is being developed through a 420-ft. shaft and a 200-ft. winze from one of the levels. The vein is in diabase and porphyry. The ore runs about 4.7% copper, 4 to 6 ozs. silver and \$4 gold. New milling equipment is being installed in an old building, which will have capacity to crush and concentrate 60 tons per day. Machinery includes a crusher, ball mill and K. & K. flotation machines, the latter being those designed by Southwestern Engineering Co., Los Angeles.

Amador City.

The surface equipment formerly used at the Amador Queen mine, near Jackson, has been moved to the South Keystone, of the South Keystone Con., a recently-formed \$1,000,000 corporation. Unwatering of the 1000-ft. North Star shaft will be immediately rushed, and a drift extended from the 600 level to open the South Keystone ore body.

Extensive repairs to the shafts and surface plants of the Bunker Hill and Keystone properties are being rushed to completion, and the respective managers expect to resume normal production at an early date. The working force is being gradually increased and everything placed in shape for an active year. Practically all the men recently on strike have signified a readiness to return to work.

Jackson.

Unwatering of the Old Eureka mine at Sutter Creek has advanced to the 850-ft. point and less difficulty is being experienced in clearing the shaft below the 800 level than was anticipated; 25 men are engaged in erection of the steel headframe and electric hoist, with a like number active in the shaft.

Examination of the St. Juneau has been completed and the engineers are calculating costs of required equipment and supplies. It is understood British Columbia people have arranged to reopen the property and develop it. It is located in the slate belt 4 miles south of Jackson, and to the west

of the Mother Lode, and has produced several pockets containing \$10,000 to \$50,000, and is said to have yielded \$75,000. Late prospecting of the slate revealed numerous seams of gold-bearing quartz. Developments consist of a 1000-ft. tunnel and numerous laterals.

Taylorville.

Preparations for building of the railroad from the Engels copper mine to the station of Paxton on the Western Pacific have been made, and construction of the line will soon start. The road will be approximately 22 miles long. The management of the Engels Copper Co. states that within a year the company will be producing 1000 tons of ore daily, placing it at the head of California copper properties in point of tonnage. Numerous additions are being made to the flotation plant, and its capacity has been increased to about 700 tons daily.

Angels.

Unwatering of the Porter copper mine, idle since 1865, is proceeding. Timbers are found in a splendid state of preservation and the workings are generally in good shape, despite the many years under water. When last worked considerable rich ore was extracted.

The Angels Camp Deep Mining Co. has installed a hoist and compressor, and is negotiating for the purchase of the Brown-Smyth-Ryland mine. If the deal materializes the 10-stamp mill on the ground will be overhauled and placed in operation. An electric transmission line is also to be built to the Pioneer shaft of the main group. Good ore is showing in new workings and the outlook is considered highly satisfactory.

Sonora.

The Springfield Development Co. has arranged for extensive prospecting of its gravel channels with a Keystone drill. Explorations by the drift method have been curtailed, but driving of the main tunnel continues. As the channels are definitely located by the drift drifts will be thrown out to open the gravel and production pressed.

Quartz mining is decidedly active in this field. All the old producers are operating full-handed, and several good prospects have been recently opened. Abundant water is now available, and the few mines that closed temporarily for want of water are again in operation.

Crescent Hill.

A quartz mill, capable of reducing 50 to 65 tons of ore per 24 hours, has been installed at the Tefft mine and will be operated by a large gasoline engine. A good tonnage of profitable ore is on the dumps and exposed underground, and it is planned to operate during the winter with a force of 15 men. With the advent of spring the working crew will be at least doubled and operations pressed along greatly broadened lines. J. F. Groover is superintendent. Crescent Hill is 5 miles south of Quincy.

Alleghany.

The Twenty-One Mining Co., with head offices at Phoenix, Ariz., has applied to the California Water Commission for authority to divert water from tributaries of Kanaka creek for mining and milling purposes. A 2200-ft. flume and 140 ft. of ditches will be used. Late work in the Twenty-One mine has been encouraging and with the arrival of spring developments will be pressed and milling facilities augmented.

Downieville.

Los Angeles people are actively developing the Morning Star and London Tunnel properties at Blue Nose and Nelson creek. New equipment is being installed and the camp improved. Clearing out of old workings is proceeding, including a 1000-ft. drift in London Tunnel territory. Work will be pressed all winter with a crew of 20 men.

A new pump is being installed at the El Oro gravel property, near Lake City. Work has been seriously hampered in the past month by an unusually heavy water flow. The pay-streak is thought to be near at hand.

The 3175-ft. tailings flume at the Kirkpatrick has been completed and connected with 200 ft. of ditches. This will facilitate removal of tailings to a desirable point, and more economical operations. During the summer much prospecting

and development work was carried forward and a large yardage of good gravel is available for mining. The water supply has also been improved.

Vidal.

Bendigo Mines Development Co. has a well developed copper and gold mine, 7 miles from Vidal station, and 15 miles northwest of Parker, Ariz. The ore occurs in deposits, lenses and irregular shoots in limestone. The copper consists of oxides and chalcocite, and the gold is mostly in free state. Ore shipments made within the last 2 years sampled 12% copper and \$15 gold. Smelter returns from 450 tons were \$15 per ton. Most of the ore thus far produced was taken from an inclined shaft 160 ft. on the ore body. A tunnel is being driven on the ore from a point in a ravine. The entire group of 8 claims is to be explored with churn drills. Lester Scott, E. M., is in charge of the work. The company's camp is close to Colorado river, and its main office is in Los Angeles.

COLORADO.

Cripple Creek.

Ernest A. Colburn purchased the properties of the Ajax Gold Mining Co. with all plants of machinery and improvements thereon, excepting the Colburn mill, at public auction. The price was \$180,400, including costs.

The Modoc Con. Mines Co., Denver, has taken over the old Modoc Mine. A 1500-ft. shaft is to be sunk. The work of sinking is to be pushed from five different levels in order that the shaft may be completed within a few weeks.

The Laura Lee has been equipped with a new electric plant. It includes hoist compressor and drills. One shift is now employed, but the second shift will soon be put on. The company is now driving a crosscut from the 200 level of the main Laura Lee shaft to cut the main east and west vein. When encountered it is planned to drift west to the junction of this vein with the cross veins, that in the past have produced good ore at shallow depth. Ore returning 2 ozs. gold has been exposed by a winze sunk below the 200 level. It is the opinion that Laura Lee will be on the shipping list by the end of November.

Hahnwald Brothers, J. Cortellini and associates have purchased the lease on the Queen Bess.

Plans for the development of the Queen Bess by the new owners are not known.

Idaho Springs.

The Empress group has been taken over by the Gilpin Tungsten Production Co. A 500-ft. tunnel opens this property at a depth of 300 ft. At 75 ft. from the breast \$150 ore was encountered in what is thought to be the Empress vein.

The Argo Leasing Co., operating 22 claims in the Dailey district, is working a force of 20 men. The machinery for the new concentrating mill being erected by the McFarland Co. is now being hauled up, the building having been finished.

The McCreedy property on which a tunnel has been driven some 200 feet, has 25 feet yet to go to reach their objective. The vein on surface shows good value in silver. It is the intention to erect a boarding house and mine buildings next spring, the lumber now being on the ground.

A small force, which is soon to be augmented, is now working under Supt. Sturdevant on the claims of the Pittsburg Con. This property has not been worked for some years but will now be reopened on a fairly large scale.

Leadville.

The Mikado is constructing new buildings and installing machinery. A 300-hp. Wellman, Siever, Morgan hoist is being installed. The pumping equipment has not been delivered and nothing of importance is being done underground. The Leadville Unit has begun pumping and only the bottom level is under water. The lift is 50 ft. from the shaft bottom to the connecting drift in the Harvard through which the water is being carried to the pumps in the Har-

ward shaft. The water has been lowered to the bottom drift in the Jamie Lee. It is said that the shaft will be free of water in the next 10 days. Following the completion of draining, sinking will be started in the Jamie Lee shaft.

Underground work at the McCormick is of a preliminary nature. New drifts are being driven to intercept the ore bodies. Some of the old drifts are being retimbered and enlarged. A new railroad switch is being put in and a trestle is being built to expedite shipping. No effort has yet been made to extract a heavy tonnage. Drainage of the Greenback will continue below the 1100-ft. level. The past several weeks have been confined to the installation of relief pumping machinery at the 1100. The sinking pump has been connected with the new station plant and resumed its task.

Silverton.

At the Kittimac snow-breaks are being built to protect the tramway towers during the winter. At the mill changes and improvements have been made. A new classifier, designed by J. M. Hyde, is in operation and gives good results. The Card tables have been relaid with Wilfley tops and hung upon new supports.

The development tunnel on the Elk Mining & Milling Co.'s property has reached a depth of 1200 ft. and in being driven encountered five veins, three of the veins being from 3 to 7 ft. wide with good milling ore. The tunnel is now passing through the last 20 ft. of the bedding plane of the vein, which is 25 ft. wide on surface. This vein is the objective for which the tunnel was driven. In driving the last 17 ft. andesite formation was encountered in which seams of ore were found carrying copper, gold and silver. Assay returns show 9% copper, \$2 gold and 4% silver. The flow of water is 850 gals. per minute. As soon as the flow has decreased sufficiently, work with a day and night shift will be started.

GEORGIA.

Dahlonega.

Louis Work, Cincinnati, owner of the Keystone Placer property, has been spending the past 2 weeks with John A. Kimber examining the property with a view of putting in a hydraulic equipment to work the property on an extensive scale.

The Crown Mountain Mining & Power Co. are running 30 stamps on ore from the Wallace and sand veins. The latter vein is opened and 20 ft. thick. The company is arranging to put in a gravity tram so as to be able to handle 200 tons per day. They will also probably add a cyanide plant to treat the tailings in the near future.

IDAHO.

Wallace.

The Rex Con. Mining Co. has purchased six claims adjoining the Rex group in the Nine-Mile district, paying \$47,600 cash and 187,000 shares of Rex Con. stock for the holdings, according to official announcement. The new property is said to be remarkably promising, considering the limited amount of development, and plans are being prepared for entering the ground at depth from the old Rex workings. The sorting plant and tramway at the Rex mine were placed in commission recently, and the mill also has been given a trial run, preparatory to beginning permanent operations. About 200 tons daily will be treated at first, but as soon as the new equipment is in thorough adjustment the capacity will be increased to 300 tons. General Manager Raymond Guyer states that a year's supply of ore of good commercial grade has been developed above the No. 2 level, and the reserves are being increased daily. It is believed that it will not be necessary to mine below the No. 2 for a number of months, leaving all the tonnage on the Rex vein below that level and on the Okanogan vein between the Nos. 2 and 4 levels for later extraction. The mine now is opened to the

No. 5 level, which is 500 ft. below the No. 2, and the bodies between these two levels are to be fully developed, while the shaft is to be sunk 500 ft. below the No. 5.

The Alameda Mining Co., which owns and is developing the Alameda mine, in the Nine-Mile district, control of which recently was acquired by Spokane men, has been awarded \$56,070 as the value of the ores alleged to have been extracted from its mining ground by the Success Mining Co., by Referee Lawrence E. Worstell, who heard the testimony in the case under appointment by Judge Woods of the district court. This award bears interest at the rate of 7% from June 1, 1913, and Nov. 1, 1916, amounted to approximately \$13,410, making the total award with interest, \$69,450. Referee Worstell finds that on or about April 1, 1912, the Success Co. commenced to extract ore from Alameda grounds and continued up to Aug. 1, 1914. The trespass, however, according to the report and findings, was committed under an excusable mistake, and the removal of such ore was through inadvertence in the honest belief that it was the property of the Success Co. The total amount of the trespass committee on the 400 stope, according to the findings, equals 25,695 cu. ft. and on the 450 level 13,442 cu. ft., while the foot-wall area on the 700 level amounted to 10,323 cu. ft. A ton of ore on the 400 and 450-ft. stopes was found to be equal to 7.49 cu. ft., which assayed 20.45 ozs. silver, 20% lead, and 23.95% zinc. On the 700 level it took 8.86 cu. ft. of ore to the ton and its assay value was 7 ozs. silver, 7.5% lead, and 25.7% zinc. The referee adopted the average prices of metals as testified to by Rush J. White as a basis for the values of the ores extracted, which were: 58.787 cts. for silver; 4.236 cts. for lead, and 5.188 cts. for zinc. It was stipulated during the trial that the mill saving was 56% silver, 72.5% lead and 65% zinc values. The Success contract in force between the first day of April, 1912, and the first day of August, 1914, was used by the referee as a basis for computing the freight and treatment charges, and that the reasonable cost of mining and milling the ore was \$2.21 per ton and that the Success Co. was entitled to those costs. In computing the amount of ores extracted from the different stopes, the referee found that 1848 tons of ore had been removed from the 400 stope, 1532 tons from the 450 stope and 736 tons from the 700 stope. The report after being handed to Judge Woods, was immediately assigned to Judge John M. Flynn, who will review the findings of Referee Worstell and file his decision thereon.

LAKE SUPERIOR.

COPPER.

Houghton.

Calumet & Hecla is steadily increasing its daily output and is now forwarding to Lake Linden about 10,867 tons, which has been increased this month up to the 16th, from 10,600. Conditions all over the district are very favorable for good tonnages this winter, as the lessons of last winter have taught both the mines and railroads to prepare for the storms that do so much damage to tonnage. Men are more easily to be had except at the most remote mines, and all of the mines except that class are steadily enlarging their forces.

Almeek has discontinued for a time its development of the Kearsarge conglomerate in order to use the men in getting out rock; but will again start up this work. The mill ran six stamps all the time, and with the overflow from the Franklin mill of the La Salle rock, operated the seventh stamp a little over half time. It is thought that the eighth will soon receive the jigs that it lacks, and it will in a very short time thereafter be put into commission as the Franklin will need all of its stamps.

Tamarack is getting out about the same output monthly, 23,000 tons. Nothing is known here as to the plans of the directors for the future. Almost all of the stockholders, as far as it can be learned, favor a management that will work in harmony with that of the Calumet & Hecla, as the two properties have so much in common. Mining men here feel that it is very unfortunate for the mine's best interests that

the Calumet & Hecla could not have secured the property, and that General Manager McNaughton thought it best to resign from its management. Supt. Been is qualified by long experience and a thorough knowledge of the mine to make the most out of its resources, which, taking into consideration the large areas of the Calumet conglomerate as yet untouched, the sands or tailings along the shore of Torch Lake, and the Osceola amygdaloid, which runs across the property even if in part at a considerable depth, are of great value.

Copper Range has so perfected the refining of its copper, which contains quite a large amount of arsenic, so that the latter is sufficiently extracted as to command the highest prices for munitions; this is being done at a rather low cost and effects a very great gain in income. The generally favorable conditions that are prevailing at the three mines of this company, especially at the Champion, will continue for quite a long time.

South Kearsarge has yet before it 2 years of life at both shafts according to the conservative statements of those officially connected with the mine, but the mining men here believe that it will take much longer to take out all of the good rock. The long life of this small mine is due to the large amount of good ground that has been found in the footwall that gave the appearance of being mostly trap. There is much more of this good ground than was at first expected.

Cherokee in the 16 ft. that has been so far opened on the crosscut that is being driven to ascertain the width of the lode and its mineral contents at the depth of 118 ft., is disclosing the same heavy grades that have been found all the way down in the shaft, and for 60 ft. in drifts. Experienced miners that have been to the bottom say it is equal if not superior to any of the amygdaloids yet exposed here.

Victoria really begins this week for the first time to mine on a sufficiently large scale to give a profit that will lead to dividends, as it puts its second 5-ton skip into commission to the bottom of the mine, the 26th level; all its previous work having been done with one of a 2½-ton capacity. It will now get out about 550 tons daily which will be increased very soon. The bottom level is, on the eastern drift, revealing the same heavy rock; the 25th east, which at first was in a mineralization that soon pinched out, is sending up the characteristic high grades, and from the 23d there was taken a carload of mass last month and another is about ready; this is, of course, in addition to the usual amount of stamp grades. It has been pretty conclusively shown that the best values have been from the 17th down, and that the mineralization is disclosing long and richer stretches with depth. Sinking was started again on the 16th from a point about 30 ft. below the 26th level. Last month there was a product of 136 tons of mineral, and for November it will be nearer 150. Now that the large construction costs, which have been paid out of the current profits with a balance going into the treasury have been taken care of, the earnings will be quite large.

Keweenaw is still being held back by the lack of men. It is hoped in 10 days to run for a shift and a half. The rock is of a low grade, as was expected, but the yield is high enough to give a good profit. Only enough work is done under ground to send to the mill an average grade of the whole mine as far as opened.

Michigan with its main crosscut has passed beyond the Evergreen lode to a distance of 446 ft. from the Butler lode, on its way to the North lodes of the South Lake; at the Ogishah every foot displays some copper, which averages commercial grades, and which with the longitudinal fissure lying about 7 ft. above the production, should be quite profitable. At the Butler lode the eastern drift is just about up to the 5th level, and there was taken out in the week ending the 11th, about 1000 lbs. of mass copper, while in the western the diamond drill is being used to explore for the mineralization cut off about a month ago by a fault. There is a pretty good average coming from this mine, as when the copper pinches out it is found in another.

Mass is slowly increasing its tonnage and hopes after a while to attain to its mill capacity of nearly 1300 tons daily. It is taking advantage of the high price of the metal

and its splendid earnings to put its plant in first class condition. It is replacing the two boilers, one of 200 hp. and the other of 250, which will be set up at the mill later, and which were at its central power plant furnishing steam for the compressor that runs the drills at both shafts and the hoisting-engine at shaft "B," with two Wilcox & Babcock boilers each of 335 hp. It is installing at the central power plant another Ingersoll-Rand compressor so that it can operate 80 drills at both shafts, and it has erected a new boilerhouse and a dry, or changing-house for the miners, both of concrete blocks, and is putting up two concrete stacks, the work on the stacks being done by the Concrete Construction Co. These improvements have been paid for as far as the money is due, from the current earnings, which will besides pay a dividend and give a balance to the surplus.

New Baltic is down 48 ft. with the shaft pit and has about finished timbering to that depth, though it has been much delayed by an inflow of water. It should cut into the ledge at any time.

New Arcadian has begun to crosscut to the New Arcadian lode on the 1500 level, a distance of about 150 ft. Its progress will be somewhat slow for a while as the dirt or rock taken out has to be hoisted two levels by a bucket, as the new rockhouse is not yet ready on account of delay in getting the crusher and the new rockhouse engine. The crusher will come from the Portage Lake Foundry & Machinery Co. The 1050 level, which has covered about 450 ft. of the 700 necessary to go to reach the New Baltic boundary, has been for some time in very rich ground, which will equal any grades yet found here.

Lake is sending to the Baltic mill about 300 tons daily, or 7000 monthly, which is giving about the same yield of 26 lbs. of refined copper a ton.

Flint Steel has unwatered shaft No. 3 about 200 ft. Nothing accurate is known about the old workings, as the maps have been lost, and there are not enough of the old reports in existence to furnish the needed data.

White Pine Extension was visited by John R. Stanton of New York, Fred and Angus Smith of Detroit, who are all directors. Carlos Van Law of Boston, who is a director of the Indiana, and who is connected with the U. S. Mining Co., is of the party. The White Pine was also included in the trip.

Algomah has been waiting for a sufficient fall of snow to get in the new boiler, as it is so much easier to take in anything of such great weight by sled, but judging from the snow we have been having it will not have to wait long. The boiler will be set up as soon as it is brought in and then sinking of the shaft will be resumed.

IRON.

Bessemer.

The Colby mine, operated by the Oliver Iron Mining Co., has ordered drills and equipment for the sinking of a new shaft. It will give greater facilities for the prosecution of mining in that portion of the property now too far away from present shafts, and will somewhat lessen the cost of mining.

Ishpeming.

Shipments have been nearly stopped by the Lake Superior mine. The cold weather has brought shipping activities nearly to a standstill. There are 400 cars of frozen ore in the Escanaba yards and this is delaying ore handling there to a great extent.

MISSOURI-KANSAS.

Joplin, Mo.

The Dick Turpin mine, located on the Riseling land, southwest of Joplin, will be started up in the near future if the owners can make arrangements with the electric company for current.

The market jumped from a top price of \$90 of last week to \$98 this week. As high as \$97 was received for

second-grade blende; \$95 is believed to be the average basis. Operators are very optimistic and many are holding their output of the past week for \$100. The shortage in electric current and weak gas this week greatly augmented the high prices, as it cut down production all over the district. Lead remains firm, selling at \$87 top price.

A new mining camp has started up southeast of Baxter Springs, Kans., or between the Galena, Kans., and Picher, Okla., camps, which is very promising; 40 to 50 drill holes having been put down, and six different tracts of ground are ready for shafts. Two shafts having been sunk, at the Blue Mound mine, and the Broom Corn mine, which show rich faces of ore. A number of companies have been formed who are prospecting, and it is believed by mining men that this camp will equal any of the Oklahoma camps in production.

R. W. Larson of Kansas City and O. W. Sparks, owners of the Yellow Pup mine at Klondike, have a rich new run of ore and renewed activity at the property is promised before long. The new development is near the old Anderson shaft, which is some distance north of the Yellow Pup mill. Operations are conducted at a depth of only about 70 ft., and it is at this depth that the recent good ground has been opened up by the Yellow Pup Co.

Operations have been started at the old Cock Robin mine on the United Zinc Co.'s land at Chitwood. The Pelican Zinc Co., capitalized at \$75,000, has just been organized, and has taken a lease on 60 acres on the north end of the United Zinc Co.'s "eighty" at this place. Ben H. Humiston of Kaneville, Ill., and Wm. Browne, of Chicago, are principally interested in the company. There is already a good concentrating plant on the property, the mill formerly owned by T. B. Osborne, and it will be put in first class condition and extensive mining operations begun.

The new mill of the Bumble Bee Mining Co. in the southwestern part of Joplin has been completed and started operations. While the ground is fairly well opened up, there is still considerable work to do, particularly around new shafts that have been put down. It is not likely the plant will be going at full capacity for some weeks. There are are four shafts in ore, all connected with the mill by tram.

Webb City, Mo.

Carmean & Squires Mining Co., one of the largest operating organizations in this district, has arranged to take over the Old Virginia mine south of Carterville, recently operated by J. F. Dexter. The Old Virginia is a sheet ground proposition and was a good producer about 8 years ago, previous to the flooding of the South Carterville field. The lease was obtained by Dexter last winter and after an examination of the ground, a new concentrating plant was started, and was completed and placed in operation about the first of March. Up until a few weeks ago steady operation was carried on, with results reputed very satisfactory.

The two properties of the St. Regis Mining Co. No. 1 at Duenweg, and No. 2 west of Chitwood, are averaging nearly 150 tons of ore weekly for their combined output. A shaft that was being sunk at No. 2 mine for air went into a rich face of zinc ore that measured 25 ft. This ore was encountered at the 170 level. A 20-acre tract has been acquired by the company at the No. 2 mine. Drill holes showed rich mines on different portions of the land. A 250-ton mill was erected several weeks ago and is now in operation. A hopper and tramway is being completed at the field shaft, and the dirt will be pulled up the tram to the big mill hopper. The mill hopper is large enough to hold dirt for two shifts milling. E. R. McClelland and associates of Kansas City own this property.

A rich drill strike has just been reported by Chas. W. Edwards and associates on a 45-acre lease of the Burch land, southeast of Duenweg. At a depth of only 60 ft. the drill went into a rich lead ground formation and continued into it for about 18 ft. At slightly more than 100 ft. a good silicate formation has been encountered, and from an old drill hole nearby, it is virtually certain jack will be found below 150 ft.

The Ground & Barnett Mining Co. at its new property, the Burch, southeast of Duenweg, has made a rich strike

of silicate. A new concentrating plant was completed some time ago and has started operation. They are hoisting tubs of dirt that contain 400 to 500 lbs. of silicate, which is considered to be a very high percentage in this district. The mill is approximately of 250 tons capacity and is one of the largest in the district, constructed solely for the cleaning of silicate.

Galena, Kans.

E. Pruitt and Fred Edwards of Galena, Kans., have opened up a good mine on a sublease of the Hurry-Up Mining Co.'s tract southeast of Galena. Considerable zinc and lead ore is being produced each week. The ore lies in disseminated ground and is believed to be the continuation of a rich face that was opened up at this level in the Hurry-Up shaft.

The Gypsy Mining Co. on a 20-acre tract of the St. Paul land at Spring City, southeast of Galena, made its first turnin last week since Sept. 4th, when operation ceased because of a bad cave-in of the drift in which the company was working at the time. A drill hole just to the west of the shaft shows a 20-ft. face of good rich silicate dirt at from 150 to 170 ft. This company has one of the most complete hand-jigging propositions ever used in the entire district. The derrick when erected was built so that a mill could be added without altering it. Work will begin soon to housing in the jigs for winter operation.

MONTANA.

Butte.

All the copper mines of the Anaconda Copper Mining Co. were closed down a few days last week because of the difficulty in moving ore. The recent cold snap froze the ore in the cars and as a result these cars cannot yet be unloaded. The ore is free in the bins at the mines, but it is impossible to move it to Anaconda under present conditions. The company's zinc properties, the East Colusa, Emma, Lexington and Poulin, will work as usual.

The Great Butte Copper Co., successor of the Butte & Bacon Copper Co., has completed its surface plant. There is a large shaft-house with two 125-hp. boilers, a first-motion hoisting engine, an air compressor, and a 70-ft. head frame. There is a machine shop and a blacksmith shop, as well as boarding house, bunk houses and the usual buildings appurtenant to a mine. The machinery is in operation, and the shaft unwatered and repaired to a depth of 420 ft. It is believed that below the 500 level the shaft is in good condition, and that the water can be tanked out and development work resumed immediately. The shaft, which is now 1025 ft. deep, will be sunk at least 500 ft., and some development work will be done on the 1000 level. There were strong indications of ore bodies when work was discontinued in 1907, as a result of the failure of the company's fiscal agent in Pittsburgh.

The Davis-Daly Co. has received information that the new Nordberg engine, which will greatly increase the hoisting capacity of the mine, has been loaded and was shipped, and the entire equipment is expected to reach here within about 10 days, and will be installed within 3 weeks after it arrives. Cable for the hoist is here, comprising two great reels good for a depth of 3000 ft.

According to the October report the Tuolumne mine produced 52 cars of ore in October which netted \$20,000. This will be increased to 92 cars in November. Several well-mineralized stringers have been cut in the Main Range mine and the installation of the new surface plant at the Colusa-Leonard Extension is progressing rapidly. The report follows: "During October, 52 cars of ore were shipped from the Tuolumne mine, netting about \$20,000. This ore is coming largely from the old gobs on the upper levels. It is estimated that there are at least 100,000 tons of ore in the old stopes which can now be worked at a profit. The winze being sunk from the 2600 level is down 50 ft. The ore in this winze has widened from 18 ins. to 7 ft. November production will be increased to 90 cars. The crosscut south from the Sinbad shaft on the 700 level is being advanced at

the rate of 9 ft. a day. This crosscut is in about 550 ft. and an additional 1000 ft. of crosscutting will be necessary to reach the south side line. Several stringers have been cut, showing strong copper mineralization and it is anticipated that one of the east and west leads will be encountered within the next 200 ft. A new station is being cut on the 700 level and an electric pump is to be installed within the next few days. The installation of the new surface plant is progressing rapidly. This work should be completed, the mine unwatered, and the sinking of the shaft started by Jan. 1."

Elkhorn.

John Lynn and associates, who have taken a lease on the Elkhorn Queen, which has lain idle for a number of years, are overhauling the steam hoist and boiler preparatory to working the property from the lower levels, where good bodies of shipping ore are known to exist.

Rothfus & Dickman of the Montana have completed the installation of electric machinery for running the mill and air compressor in both the Montana and Dolcoath tunnels, and everything is in readiness to start up as soon as the power can be turned on.

The East Butte is working about 20 men and shipping a car a day to East Helena. The cave-in which occurred a few days ago has been cleared and caught up and everything is running smoothly again. They are expecting a large transformer soon and when it is installed and the electricity is turned on, the steam hoist will be replaced by an electric hoist and compressor. They are also getting in material for the concentrator and cyanide plant, the erection of which will be begun as soon as certain details of construction can be worked out.

At the Elkhorn Bulwer, the crosscut from the 200 level toward the shoot of high-grade copper ore on which a winze was sunk last spring, is being driven as fast as possible, and according to the survey should be encountered within the next 8 or 10 ft.

Superior.

The Richmond Mining, Milling & Reduction Co. has purchased a half interest in the St. Lawrence group, adjoining, according to Martin Woldson, president of the Scandinavian-American bank of Spokane, who also is president of the Richmond Co. The St. Lawrence holdings were owned by the Finch-Campbell estates of Spokane and Dan and Angus Sutherland of Wallace, and the Richmond Co. has taken over the Finch-Campbell interests. Production at the Richmond is to be increased immediately to a car of ore daily, according to President Woldson. A contract for transporting the output to the railway at Salt Lake has been let to S. K. Fitzhugh, who reached the camp Sunday with eight 4-horse teams. About 1000 tons of shipping ore has been broken down in the stopes ready for extraction, and this will be removed at once. A tunnel has been driven through St. Lawrence ground jointly by the Richmond and St. Lawrence companies into the Richmond lines, and a contract, giving the Richmond interests perpetual right to the use of this working, has been filed at Superior, Mont.

NEVADA.

Goldfield.

The new raise from the main drift at a depth of 880 ft. in the Jumbo Junior is advancing in ore of good grade, indicating the ore shoot extends into the Kewanas mine. The winze on the vein near the Jumbo Extension line shows rich ore and the management is arranging to prospect it at further depth from one of the levels of the Jumbo Extension. This will open the contact where most of the bonanza deposits of the district have been encountered.

Because of the low grade of the developed sulphide ore, and the unsatisfactory results attending the treatment of oxidized material with flotation, the Florence mine has been closed and the flotation unit shut down. It is stated the directors are considering resumption of deep mining, as large deposits of sulphide ore, suitable for treatment by flotation, are indicated below the 530 level. It is also reported the

company is contemplating leasing a portion of the mine, and may arrange for treatment of its oxidized ores at the cyanide mill of the Goldfield Con., as soon as the latter company resumes with its 1000-ton flotation plant. It is expected this unit will be in commission before the end of December.

Thompson.

It is unofficially stated that the smelter of the Mason Valley Mines Co. will be blown in at an early date. The company has secured assurances of large quantities of custom ore, in addition to its own product, and will also treat a heavy tonnage from California properties. Experiments with the 10-ton leaching plant have been so satisfactory that arrangements have been made to enlarge its capacity and treat both carbonates and sweet-roasted sulphides. Custom ore will include copper, gold, silver and lead ores from numerous properties around Yerrington and in the rapidly-developing Reservation Hill field.

Toulon.

The Humboldt Nevada Tungsten Mines Co. has placed its concentrator in operation and is treating 75 tons of high-grade ore daily. A large tonnage is available, and the management has arranged for the development of large areas adjoining the proven ore zone.

Seven Troughs.

Ore assaying \$200 is being mined on the north end of the 1700 level of the Seven Troughs Coalition. A new winze is going down from this level, and another lateral will be extended from the 1800-ft. point. Since the installation of the new pumping plant no trouble has been experienced with water, and a steady output has been maintained. Developments are active at several points.

Virginia City.

All the mineral holdings in the West Comstock district, generally known as the Jumbo field, have been taken under bond and option by the C. E. Jury Syndicate of Toronto, Can. The consideration is stated to be \$500,000 and arrangements are being made for extensive explorations with diamond drills, under supervision of Charles Bayercroft. Holes will be sunk to a depth of 1500 ft. and the entire field thoroughly prospected. Among the most important properties are the Bargo, T. & E., Fluck & Mahoney, and Gates. Considerable high-grade gold ore has been extracted, particularly from the Bargo.

Goodsprings.

The Akron and Bill Nye properties, on the west side of Columbia mountain, have been merged into a consolidation known as the Goodsprings Bill Nye Mining Co. The Bill Nye has been shipping zinc and lead ores at a good profit for several months, and considerable zinc and silver ore has been sent out from the Akron which is a comparatively new proposition.

Engineers of the Salt Lake Railway are inspecting the district with a view of broadening the railroad from Goodsprings to Jean, and the possible extension of the line to the mines on the west side of the Columbia mountain range. A number of good properties have been developed lately in this field that are hampered by unsatisfactory transportation arrangements.

The working force at the Oro Amigo has been increased and a heavier output will be maintained in future. The new vein is yielding ore ranging from 10 to 45% copper, with some gold and platinum. The product is stated to closely resemble the ore found in the Boss mine. President S. E. Yount, of Los Angeles, is personally directing improvements.

Roach.

Mojave Annex Tungsten Co. is opening a vein of tungsten ore in granite rock, and has on its group the croppings of other veins. The property is in Clark Mountain district, 12 miles from Roach. Development by adit levels and surface work on the main vein show 2 to 4 ft. of mineralized gangue, running 4 to 5% wolframite. Joseph B. Evans, manager and mining engineer, Los Angeles, states that a small concentrating mill is to be erected. This will require a crusher, a set of rolls and Stebbins dry concentrators.

Mojave Tungsten Co., for which Foster S. Naething is manager, has 30 claims in Clark Mountain district, and is operating through three shafts. One of these is 180 ft. deep,

the others 100 ft. each. Gasoline engines are used for hoisting. The shaft first named is to be sunk 100 ft. deeper. The group has two systems of veins. One consists of narrow veins on which there are croppings of ore; the other consists of wider veins on which all minerals have leached out down to a depth of 30 ft. These vein systems run at right angles to each other. The tungsten ores consist of wolframite and scheelite, and carry an average of 15% of these metals. The company is operating a small concentrating mill, making jig and table products, grading about 50%. The necessary supply of water is obtained in the mine.

Las Vegas.

There has been millions in gold and silver produced in Eldorado Canyon. Some of the properties are being developed very profitably, others have equally as good showings and are awaiting the time when capital will interest itself in the further exploitation and development of these mines. Practical mining knowledge was responsible for the placing of the Colorado Nevada, Techatticup and Rand in the producing column and for bringing the Enterprise, Carnation, Lombard, Woods Lease, Empire, Skylard, Lucky Jim and others to their present state of development. It is believed that good percentage of these will be placed on the producing list before long.

The mine making conditions are here, the geological formation is right, the country has all the earmarks of a big mining district. The district has been proven for 8 miles in length and several in width, being dotted with producing mines.

The Canyon's present production, considering the small amount of development done, is without a parallel. The day is not far distant when its mineral resources will be fully explored and determined.

NEW MEXICO.

Mogollon.

The road through Mogollon is being macadamized and placed in shape to accommodate heavy traffic in winter.

D. E. Bearup, owner and operator of the Eureka mine, in which a rich strike was recently made, is arranging to pack an accumulation of mill ore to local custom works. The richer ore is being sacked for shipment to smelter.

Timbering of new shaft below the 500 level in Last Chance mine is progressing rapidly, the work being conducted from two different points. The shaft is 960 ft. deep. Development will be pushed from both 800 and 900 levels as soon as timbering will permit. The Mogollon Mines Co. is operating the property.

Socorro Mining & Milling Co. has installed an automatic scale at mill terminal of aerial wire rope tramway from Pacific mine for weighing all ore received from latter property. A belt conveyor is being placed to handle this ore between receiving bins and crusher.
